Due to the dominant user needs of governments and organized industries, official statistical sources mainly provide data about the economic dimension of communications and media. Collecting economic information, NSI, and other official sources are obliged to consider internationally agreed classifications on industries and products and to hold individual data confidential. The consequence is a lack of data, both on the national and the supranational level. The main limitations are as follows:

- lack of microdata on detailed breakdown of turnover, cost structures, and employment of communications and media enterprises, as well as aggregated data for small regions or countries;
- lack of aggregated data on markets, due to the dominance of the institutional approach in production output statistics;
- insufficient aggregated data on 'old' media industries which are not in the focus of policy action programs, e.g., print media;
- a general lack of data on 'new' communications and media industry or products, due to a 5-year revision interval for international activity and product classifications;
- lack of data on nonprofit organizations or individuals producing media content (e.g., so-called 'user-generated content'); and
- finally, a general lack of microdata and aggregated data on media content or media use due to the lack of international classifications for cultural statistics. (The only exception is time budget data, but the main category 'use of mass media' is not very feasible, due to the fact, that about half the time spent on media use is parallel to other main activities.)

To some extent, reports on behalf of governments, political advisory councils, parliament commissions, or expert groups contain data that are suitable for social research on the cultural, political, and social dimensions of communications and media. However, these data are not collected on a regular basis, and unique national statistical categories are used.

Insufficient Data of Nonofficial Sources Arising from a Diversity of Statistical Classifications and Altering Collection Methods

Numerous nonofficial sources provide aggregated data on old and new communications and media markets, as well as

microdata on communications and media enterprises, on individual media use and – on a minor scale – media content. Many of these data providers only offer data on a national level using their own statistical classifications. This leads to severe constraints for secondary analyses in social research.

One methodical problem arises from the tendency of industry associations and commercial data providers to change their classifications and data collection methods very frequently. This means that one has to be careful when using data from nonofficial statistical sources for time series analyses, even on the national level. A break in a statistical trend may be a statistical artifact due to altered statistical categories or data collection methods, and not the result of changing behavior of providers or users of communications and Internet services or media content. In 2000, for example, the interview technique of Germany's largest annual audience survey (media analyze) changed from personal face-to-face interviews to computer-assisted telephone interviews (CATI). A sharp rise in the level of radio listening time per adult of nearly 30 min per day was the result.

The different national statistical categories and collection methods also have a negative effect on the usability of the data for cross-country studies. Supranational nonofficial sources that claim to provide harmonized international data, by altering the original national data, have to be checked thoroughly. One example is data published on the time spent on different media. It is collected by either diary methods, personal interviews, or telephone interviews. There is clear evidence that the chosen method has an impact on the results. Another good example is the above-mentioned annual WARC report on international advertising markets. Some national advertising associations collect the so-called 'net' advertising turnover figures (i.e., without deductions and commission charges) directly from media companies. In other countries, commercial companies measure advertising volume (number of advertising spots or ad pages) and estimate 'gross' advertising expenditures by multiplying the volume figures with the official media tariffs, announced by media companies. However, in reality most of the advertising time and space is sold much cheaper. To harmonize data from different countries, WARC estimates the gross–net difference, but is not very successful in doing so. (In Germany, for example, both methods to collect data on advertising expenditures are in use. In 2012, the gap between published 'net' TV adverting figures and published 'gross' TV adverting spending was 70% while the estimate of WARC was 20%.) To avoid the production of statistical artifacts, all cross-country studies using data from supranational nonofficial sources should demonstrate whether the collection method has no statistically significant effect on the empirical results.

Conclusions

From the perspective of social research, the data on communications and media provided regularly by official and nonofficial statistical systems have some essential limitations. Some arise from a lack of data provided by official sources, particularly for detailed market data and indicators describing the cultural, political, and social dimensions of communications and media. This 'availability gap' is partly filled by nonofficial sources. However, data from industry associations or commercial data providers underlie some severe methodological limitations, which should be explicitly discussed when used in secondary analyses.

To improve this situation, social researchers should exert influence on official statistical sources in two directions – to facilitate the access to microdata on communications and media enterprises, and to develop international classifications not only for the use of advanced IC technology but also for statistical indicators on traditional mass media. The opportunities of researchers to exert influence on statistical classifications or collection methods of nonofficial sources are more limited. Nevertheless, a broader discussion of the methodological limitations, particularly of sources used frequently for cross-country analyses, might help to improve the outcome of these research projects.

Abstract

Mass media, criminal justice system officials, and policy-makers all rely on crime statistics to make claims about crime levels and trends; legislators and criminal justice system officials use them to implement policies to address crime; and criminologists and other social scientists use crime statistics to conduct research on the causes of crime, to inform theories of crime, and to evaluate the effectiveness of crime control policies. In this article we discuss the three primary sources of crime statistics: official data (Uniform Crime Reports and the National Incident-Based Reporting System), victimization studies (National Crime Victimization Surveys), and self-report studies, focusing on their basic methodology and the various problems associated with their compilation.

Official Crime Data

Official crime data are derived from several functions of the criminal justice system, including police reports of offenses and arrests, charges filed by prosecutors, criminal complaints and indictments, imprisonment data, and prison releases. The first national crime statistics, based on judicial data, were published in France in 1927. In the United States, despite attempts by the Federal Bureau of the Census to collect crime statistics, as early as 1907, it was not until 1930 that such statistics became available at the national level. Due to space limitations and the fact that they are more widely used in discussions of trends and variations in crime across jurisdictions and over time, we focus here on two major sources of police data on crime – Uniform Crime Reports (UCRs) and the National Incident-Based Reporting System (NIBRS).

Prior to 1930, police reports of crime in the United States were not collected or compiled in any systematic way across jurisdictions. Some cities kept yearly counts of reported crime incidents and persons arrested, while other cities did not formally record such information. There was also widespread variation in the classification of crime across jurisdictions, with different community standards and legal definitions affecting how crimes were defined and whether particular activities were officially recorded as crimes. As such, both comparisons across jurisdictions and estimates of historical crime trends are problematic prior to 1930 due to the lack of uniformity in crime definitions and data collection.

In developing the UCR program in the late 1920s, the International Association of Chiefs of Police recognized that not all crimes were equally important. They therefore focused on seven types of crimes that were prevalent, generally serious in nature, widely identified by victims as criminal incidents, and most likely to be reported to the police. The original seven 'index' crimes (also referred to as 'Part I offenses') are murder and manslaughter, forcible rape, robbery, aggravated assault, burglary, larceny, and motor vehicle theft. Arson was added to the UCR as an index crime in 1979. Twenty-one less serious crimes and status offenses are classified as nonindex or Part II crimes.

The FBI compiles UCR data from law enforcement agencies and publishes annual data on crime and arrests broken down by age, sex, and race of individuals arrested, and the city and region of the country where the crime was committed. Although participation in the UCR program is voluntary, the proportion of law enforcement agencies that submit data to the program is impressive. A total of nearly 18 000 state, county, and city law enforcement agencies, covering more than 288 million US residents, submitted crime reports under the UCR system in 2008. A total of 95% of the US population is covered by this data source, with law enforcement agency participation rates being slightly lower in cities outside metropolitan areas (88%) and in rural areas (90%).

Two essential components of the UCR data system involve the classification and scoring of criminal offense. Classifying crime offenses in the context of the UCR refers to the process of translating offense titles used in particular local and state laws into the standard UCR definitions for Part I and Part II offenses. Scoring of offenses refers to counting the number of offenses after they have been classified under the UCR typology and entering the total count.

Classifying crimes can be a complex process, and there are several sources of ambiguity in the definition and coding of offenses that call into question the uniformity of reporting practices across jurisdictions. The primary sources of variability include differences across jurisdictions in their interpretation of crime incidents, the hierarchy rule, the diligence of record keeping, and the adequacy of follow-up procedures.

To take just one example of this ambiguity, in the specific case of homicide (widely believed to be the most reliably coded crime), the main obstacle to uniform reporting and counting involves the follow-up procedures, the timing of police investigations and UCR filing, and definitional issues in the classification of accidental killings and justifiable homicides. For example, the recording of situations of aggravated assaults that eventually become murders because the victim dies as a result of the assault assumes equal diligence and detailed record keeping across recording agencies in conducting follow-up investigations and correctly adjusting multiple monthly returns. Some less diligent law enforcement agencies may

simply count the aggravated assault and fail to record the subsequent death of the victim as a murder.

An interesting example of the confusion that can occur with respect to the coding of homicides comes from New York City, which, in 2006, saw an apparent increase in homicides from the previous year. However, part of this increase was created by an unusual number of deaths that were classified as homicides because the city's medical examiner determined they were related to crimes that had been committed in earlier years. Of the 25 such reclassified deaths in 2006, 12 were related to injuries that had occurred at least 14 years earlier, including a 72-year-old man who was shot in 1974 and died of pneumonia in 2006 (Vasquez, 2006).

The UCR's hierarchy rule applies to the classification and scoring of crimes when multiple offenses are committed at the same time. When the hierarchy rule is applied, only the most serious offense in the series is reported, and all others are not counted. For example, if an individual breaks into a house, steals items from the house, kills the owner of the house, and makes a getaway in a stolen car, only the murder will be recorded in official statistics, as it is the most serious offense.

National Incident-Based Reporting System

A relatively recent enhancement to the UCR program is the development of the NIBRS. In contrast to the UCR, which uses a summary or aggregate reporting approach, NIBRS categorizes each incident and arrest in one of 22 basic crime categories that span 46 separate offenses. A total of 53 data elements about the victim, property, and offender are collected under NIBRS (Maxfield, 1999). Although NIBRS data have been used in federally published reports on crime, as of 2012, 6115 law enforcement agencies (representing only 33.4% of all agencies) participated in the program, and more than half of the participating agencies were located in cities with fewer than 10 000 inhabitants (FBI, 2013). The low rate of participation in NIBRS by law enforcement agencies in more populous jurisdictions has led to questions about the accuracy of estimates of crime that derive from these data (Addington, 2007). And despite its promise in terms of improving the accuracy of crime statistics, several problems exist with NIBRS data. First and most obvious is the complexity of the coding scheme, which is documented in four volumes published by the FBI. Because many police officials may be less than diligent in following these coding requirements, missing data may be an even greater problem under NIBRS (Maxfield, 1999). In addition, because NIBRS eliminates the UCR's hierarchy rule, its adoption may lead to an increase in reported crime, creating potential public relations problems for law enforcement agencies which are, to at least some extent, evaluated on the basis of crime rates in their jurisdictions.

Problems with Police Data on Crime

Police reports are often considered to be the best official measure of the nature and extent of crime. Compared to prosecutorial, judicial, and correctional data, police reports are more comprehensive in their coverage of types of criminal offenses and include information on criminal incidents even when the offender has not been identified. However, as a measure of the true extent of crime in a jurisdiction, police statistics are inadequate for several reasons. The major problems with police data involve variation in citizen reporting of crime and police recording practices, possible race, and social class biases in the structure of policing, limited coverage of crime types under UCR data, conceptual and methodological factors that affect the classification of crime incidents and estimates of national crime rates, and political manipulation of these data by police departments.

The term 'dark figure' has been used by criminologists to represent the gap between the true extent of crime and the amount of crime known to the police. The primary sources of this gap are the inability of police to observe all criminal activity, the reluctance of crime victims and witnesses to report crime to the police, and variation in the recording of known crime incidents due to police discretion.

Although it is not well known, the vast majority of crime becomes known to the police through citizen complaints or calls for service and many citizens choose not to report crimes they have experienced. In fact, in 2012, only 44% of violent crime victims and 34% of property crime victims reported the incidents to the police (Bureau of Justice Statistics, 2013). The reasons why victims and other citizens do not report crimes to the police include a lack of trust in the police or reservations regarding the ability of police to solve crimes, and fear of retaliation and/or reprisals from offenders for reporting crime. In addition, the victims in some crime situations may also be involved in criminal activities themselves (e.g., drug sellers or prostitutes who are the victims of robbery), which decreases the likelihood of reporting.

Even if a crime is reported by citizens or directly observed by the police, there is no guarantee that such an offense will be recorded in official data. Police discretion, both across and within jurisdictions in recording an incident as a crime is a major source of inconsistency in official crime data. Donald Black (1970) notes that the police are more likely to file an official report if the crime is serious in nature, if the complainant prefers arrest (as opposed to informal action), if the criminal incident involves strangers rather than friends of family members, if the complainant shows deference toward the police, and if the complainant is of higher social status. There is also considerable evidence to suggest that race and social class biases exist in street-level policing, which may explain at least some of the difference between minority and white crime rates.

An additional and important limitation of official crime statistics involves their manipulation and fabrication for political purposes. Because the police have exclusive control over the dissemination of crime data and there is infrequent monitoring of the accuracy of their crime counts, one way to demonstrate effective law enforcement is to distort, manipulate, and fabricate the number and nature of crime reports. Local agencies can 'cook the data' through a variety of procedures, including not reporting all crime incidents, counting separate events as if they occurred in multiple offense incidents, declaring reported crimes as 'unfounded' so they are not counted in annual UCR summaries, and downgrading Part I (index) offenses to minor offenses so that they are not tallied nationally in the UCR summaries.

Numerous examples of fabrication of crime statistics have been identified, including in several major US cities (e.g., Atlanta, Philadelphia, Los Angeles, Detroit, Dallas, Phoenix, Milwaukee, Washington DC, New York, and Chicago). In New York, substantial reductions in crime rates over the 1995–2010 period have been attributed to aggressive and effective law enforcement practices, however, critics have alleged that at least part of this decline in crime rates is due to pressure from police management to reduce officially recorded crime (Silverman and Eterno, 2012). A more recent example of this manipulation comes from Chicago, where, according to data published by the police, the number of index crimes decreased by 56% over the 2010–13 period. However, an audit by the city's Inspector General found that the Chicago Police Department had undercounted aggravated assaults by 24%, and police sources indicated that they had been pressured by their superiors to underreport crime by misclassifying or downgrading offenses, counting multiple incidents as single events, and making it more difficult for people to report crime (Bernstein and Isackson, 2014).

Official Crime Data in International Context

The two major sources of international crime data are from the International Police Agency (Interpol) and the United Nations. Interpol crime reports are published in four languages (Arabic, English, French, and Spanish) and include data on murder, sex offenses, serious assault, theft, aggravated theft (robbery and violent theft and breaking and entering), theft of automobiles, fraud, counterfeit currency offenses, and drug offenses. Although these Interpol data are provided for multiple countries, Interpol reports provide cautions about the appropriateness of using these data for cross-national crime comparisons. This caution is necessary because the statistics do not account for definitional differences in crime categories across various countries, the diversity of methods used by different countries in compiling the statistics, and changes in laws or data collection procedures over time. In addition, as revealed from the International Crime Victimization Survey, the proportion of crime not reported to law enforcement varies substantially across nations and with respect to different types of crime. Similar problems exist in using the United Nations Crime Surveys for cross-national comparisons.

Victimization Surveys

At least partially in response to concerns about the limitations of official crime data, victimization surveys, which ask people about their experiences as victims of crime, were initiated. The first large-scale victimization survey in the United States appeared in the late 1960s, and since that time, they have been widely used to measure the frequency and characteristics of particular types of crimes and the demographic profiles of victims, both in the United States and in other countries. By eliciting information about both crimes that citizens report to the police and those they do not, victimization surveys provide further information regarding the dark figures of crime. Data from these surveys have also been widely used to develop and modify theories of crime.

As implied by the basic definition, these surveys involve self-reports of victimization experiences by victims themselves, and as such, are subject to many of the same problems associated with other forms of survey research more generally. Victimization reports are usually generated from random samples of the general public, and a variety of screening questions are used to identify different types of victims. A number of crimes captured in other data sources (for example, prostitution and alcohol and other drug offenses) are not covered in these surveys because such crimes are considered to be victimless. In addition, in some crime situations, it is not feasible to interview the victim – an obvious example would be in a situation of homicide. Finally, some crimes, such as vandalism, are viewed as trivial and are not covered by victimization surveys; others, such as white-collar and corporate crime, are seen as difficult to measure accurately. The lack of coverage of certain types of crimes makes direct comparisons between victimization and official data problematic.

The National Crime Victimization Survey (NCVS) is the most comprehensive and systematic survey of victims in the United States. The sampling procedure is supervised by the U.S. Census Bureau; the survey is conducted by well-trained staff and interviewers; and changes in the sampling design and format of questions are rigorously evaluated in terms of their effects on estimation of victimization experiences.

With respect to the selection of households to participate in these surveys, with the goal of obtaining a nationally representative sample, the NCVS uses a complex, stratified, multistage cluster sample, with what is known as a rotating panel design. This means that sample households are organized in panels and each panel is divided into six groups so that interviews are ongoing throughout the year, thereby reducing seasonality effects. Residents of sample households are interviewed a total of seven times – once every 6 months for 3 years – and once seven waves of interviews are complete, the panel is rotated out of the sample and replaced by new households.

Crime incident reports in the NCVS involve a series of questions about the particular crime event (that have occurred in the previous 6 months), the offending parties, and the consequences of the crime. For each separate victimization incident identified by the respondent, they are asked whether the crime was reported to the police; whether the offense was completed or merely attempted; whether the offender was identified or known to the victim; the demographic (race, gender, age) characteristics of the offender (if known); whether a weapon was used in the crime; whether the offender was a member of a gang or under the influence of alcohol or other drugs at the time of the incident; whether the victim resisted; and the amount of monetary loss or physical injury (or both) that resulted from the victimization.

Similar to the other two major sources of crime statistics, victimization surveys are susceptible to conceptual and methodological problems that call into question their accuracy as measures of crime. In addition to the fact that they do not cover all crimes that may be of interest to criminologists and policymakers, victimization surveys are subject to sampling bias. For example, particular groups of people are less likely to participate in these surveys than others, and the excluded groups tend

to be more prone to victimization. In the NCVS, homeless persons, young males, and members of minority groups are less likely to be included, and each group has higher rates of victimization than their older, female, and nonminority counterparts. At the other extreme, the very wealthy are likely underrepresented in victimization surveys because of their ability to isolate themselves from interviewers. The exclusion of victimization experienced by businesses and crimes against the government in household victimization surveys can also be viewed as a source of sampling bias that dramatically lowers estimates of national victimization rates.

Another problem with victimization surveys is related to the fact that a variety of factors influence participants' responses, including question wording and reference periods, and basic limitations of human judgments. Both incident rates and subgroup variation in victimization risks are affected by the particular screen questions used to elicit reports of victimization experiences. Short screen questions may cue a respondent's recall of only a small subset of incidents that involve the most serious or frequent violations, whereas longer screens encourage the recounting of a fuller range of experiences. With respect to reference periods, surveys that use a reference period of 1 year or more are susceptible to forward telescoping (i.e., remembering events as occurring more recently than they actually occurred). The 6-month reference period used in the NCVS makes this survey prone to backward telescoping (i.e., remembering incidents as having occurred in a more distant past).

Victimization surveys are also an imperfect measure of crime because of the inherent fallibility of human information processing and judgment. People experience lapses in memory, selectively perceive and misperceive particular actions, and interpret actions and events from their own perspectives. In the case of reports of victimization, people may overestimate or underestimate their experiences through outright deception, exaggeration, embarrassment, or misinterpretation.

Self-Report Studies

Self-report studies of crime were developed in the 1940s and 1950s, largely in response to concerns among criminologists that official measures of crime were systematically biased and provide a distorted picture of the nature of crime and its correlates. Although there are exceptions, self-report surveys are typically administered to youth populations, and among the most prominent and widely used self-report studies in the United States are included the National Youth Survey (NYS), the National Longitudinal Study of Adolescent Health (Add Health), the Monitoring the Future Survey, and the National Household Survey on Drug Abuse (now known as the National Survey on Drug Use and Health). Although there are variations in the specific methodology of each of these studies (and other self-report studies) in order to illustrate the general principles of self-report studies, we briefly discuss the NYS.

First conducted in 1977, the NYS was designed specifically to provide both prevalence and incidence estimates of the commission of delinquent activities by youth. It is a longitudinal survey that uses a national probability-based sample of young people who were 11–17 years old at the time of the first interview. Participants in this study were interviewed in their homes at 1-year intervals through 1981 and at 2–3-year intervals at least through 1995. More than 90% of the original 1725 participants have remained in the NYS over time.

The methodology of the NYS involves confidential, face-to-face interviews to solicit information on the number of times the respondent has engaged in a specific delinquent or criminal activity within the past calendar year, with two different response sets used. If an individual's response to an open-ended question indicates that they have engaged in the particular activity (e.g., destroying property, carrying weapons, physical assault, using or selling drugs) more than 10 times, the interviewer asks the youth to select one of the following responses: (1) once a month, (2) once every 2–3 weeks, (3) once a week, (4) 2–3 times a week, (5) once a day, or (6) 2–3 times a day. Although described in nonlegalistic terms, the 47 activities asked about in the NYS directly parallel offenses listed in the FBI's UCR. Of the Part I offenses, only homicide is excluded; about 75% of Part II offenses are included, along with a wide range of misdemeanors and status offenses.

Collectively, since their inception in the 1940s, self-report measures have consistently revealed dimensions of crime and its correlates that were either at odds with or could not be addressed by official statistics. For example, in self-report surveys, girls and women report being just as delinquent and criminal, although less frequently and intensely, as do boys and men. Whites similarly admit to involvement in a range and number of delinquent and criminal acts closely paralleling that of blacks. Middle- and upper-class youth self-report similar levels of involvement in delinquent activities as lower-class youth.

Self-report data, however, are by no means without their weaknesses and are subject to problems of reliability and validity. These data are constrained by the same elements that affect self-reports of all types of behaviors – respondents to surveys often give inconsistent or incorrect answers. The form of the question, the choice of words in the question, the response categories, and the position of the question in a series of items can affect what respondents think the question means; people may also answer incorrectly because they do not remember certain things. As such, significant underreporting of crime and deviant behavior can occur on self-report surveys, and there are some indications that members of minority groups (in particular, African-American males) are more likely to underreport their involvement in crime (Thornberry and Krohn, 2000). On the other hand, there is evidence that some people will overreport their involvement in criminality and deviance on these surveys (Mosher et al., 2011). With respect to validity, some critics have noted that self-report surveys tend to focus on relatively trivial, noncriminal acts and behaviors (such as skipping school) and as such are not directly comparable to official crime data.

A useful check on the accuracy of self-report data involves comparisons of respondents' self-reports of drug use to the results of urinalysis tests in the Arrestee Drug Abuse Monitoring (ADAM) Program administered at local jails in the United States. Under this program, inmates are asked a series of questions regarding their use of particular substances (among other questions) and are also subject to urinalysis tests. Data from ADAM reveal that there is generally a higher concordance

rate for marijuana use, that is, more arrestees will truthfully report the use of this drug. However, underreporting is much more common for harder drugs such as heroin and cocaine. For example, 1998 ADAM data from New York City indicated that 47% of arrestees reported using cocaine, but 75% had positive urinalysis results for the substance (Golub et al., 2005). The findings of differential honesty in reporting by type of illegal substance is consistent with what is known as 'social desirability theory,' which suggests that the distortion of self-reports, by under- or overreporting, is related to the acceptability of the behavior in question (note that this principle would also apply to behaviors other than drug use) (Edwards, 1957). Because the use of marijuana is less stigmatized than the use of hard drugs, respondents may be more likely to truthfully report using the substance.

What the Data Tell Us about Crime

Official data and victimization surveys reveal somewhat different patterns with respect to trends in crime rates in the United States. Crime rates as measured by the UCR increased substantially between 1960 and 1990, and have declined since the mid-1990s – this pattern has been similar for both violent and property crimes. However, annual crime victimization surveys show trends that are qualitatively different from those based on official police data. Specifically, the victimization data reveal that violent victimization rates remained fairly stable between the early 1970s and the mid-1990s, before declining in a similar fashion to the trend revealed in the UCR data. In contrast to the pattern of an increase followed by a decrease in property crimes shown in the UCR data, victimization surveys indicate that property crime has exhibited an essentially continuous decline since the mid-1970s. This slight contradiction in crime trends based on comparisons of UCR and NCVS data is largely the result of differences across these methods in their coverage of crimes, rules for counting crime incidents, and the population base from which crime rates are calculated.

The convergence of findings across the various methods of measurement is more pronounced with respect to the nature of criminal offenses. Contrary to impressions derived from mass media coverage of the issue, all three sources indicate that most crime in the United States involves relatively minor property offenses (as opposed to serious violent offenses) that occur with considerable frequency. In addition, the vast majority of violent offenses are attempts or threats that involve little or no injury to the victim. It is important to emphasize, however, that none of the three sources of crime statistics provide information on white-collar or corporate crime, organized crime, or crimes committed by governments and their agents.

In terms of the social distribution of crime, all three sources generally indicate that criminal offenders are disproportionately young, male, and members of ethnic or racial minority groups. UCR data indicate that approximately 15% of those arrested are under 18 years of age, 76% are male, and 28% are black. Although the differences across some groups are less pronounced, the NCVS data reveal similar patterns with respect to the demographics of criminal offenders. Smaller differences by age, sex, and race are found in studies of self-reported criminal behavior.

To conclude, all three primary sources of crime statistics – the UCR, victimization, and self-report studies, are characterized by methodological weaknesses. It is important for consumers of these data (including legislators, criminal justice system officials, and mass media) to adopt a healthy skepticism in interpreting crime data.

Abstract

Criminal and delinquent behavior is inherently difficult to measure because it is surreptitious behavior and most crimes are never reported to the police. This article reviews the primary methods used by criminologists in the United States to measure criminal and delinquent behavior, and describes the advantages and limitations of each method. It provides historical context to the development of crime statistics and identifies some of the major sources of data on crime and delinquency available today.

Introduction

Crime and criminal justice statistics serve many audiences and many purposes. Journalists use crime statistics to report putative levels and changes in crime to the general public. Academics rely on them to investigate the causes of crime, as well as its spatial, temporal, and demographic features. Statistics from law enforcement agencies (e.g., police, jails, courts) are used to assess the effectiveness, efficiency, and fairness of those institutions. Politicians often use crime statistics to frighten or mollify the public to their own political advantage, while popular magazines rank cities according to their ostensible safety. Private organizations like rape crisis centers and domestic violence organizations use them to assess their effectiveness or to justify their existence. As with statistics on unemployment or public health, crime statistics often carry great weight, defining places or periods as dangerous or safe, even when those characterizations may be unwarranted.

Like other social statistics, crime statistics carry an aura of precision and accuracy that is alluring to many. 'Crime rate drops 9% last year.' 'Police clear 56% of homicide cases.' But like all social statistics, crime statistics are the outcome of complex processes that entail many potential sources of measurement error. Intelligent users need to understand and appreciate the uncertainties that inhere in such statistics, and their implications.

This article concentrates on the ways that criminologists measure crime and, in so doing, attempt to circumvent or overcome the inherent difficulties in measuring such behavior. Perhaps the chief difficulty is that criminal behavior is surreptitious behavior. Those who engage in it actively seek to hide their identity and their behavior from public and law enforcement scrutiny. This, along with other problems, makes the measurement of crime particularly difficult and, at times, impossible or unethical.

Official Crime Statistics

Uniform Crime Reports

As part of their public mandate, most police departments and other law enforcement agencies issue regular statistical reports. In the United States, the vast majority of local police departments submit data annually to the Federal Bureau of Investigation (FBI), which compiles and summarizes the data each year in a report entitled 'Crime in the United States: Uniform Crime Reports (UCR).' The UCR strives to standardize definitions of crimes across states and reports the number of offenses known to the police; the number of arrests; and clearance rates for counties, metropolitan areas, states, and the nation as a whole. The UCR covers a wide range of offenses, including violent offenses like assault and rape and property crimes like burglary and larceny, and it has its counterpart in many other countries, from Australia to England to Germany.

Established in 1929, the UCR is the oldest crime reporting system in the United States, and it was for decades the sole source of crime data for journalists, criminologists, and others. Even today it remains widely used by journalists interested in reporting crime trends and related topics. With a few exceptions, however, UCR data are plagued by numerous forms of systematic measurement error. By nature, UCR data are reactive, meaning that they rely on victims and witnesses to report crimes to the police. This requires citizens to both interpret an event as a crime and decide to report it to the police. For a variety of reasons (e.g., fear of reprisal, lack of confidence in the police, fear of social stigma), most crimes that take place in the United States are never reported to the police. This problem is so severe that the UCR itself acknowledges it and cautions users against inappropriate inferences from their data, such as ranking cities and counties by their crime rate. Other problems pertain as well. For example, in criminal events that involve more than one crime (e.g., a residential burglary that includes assault and rape), the UCR records only the most serious offense, thereby systematically undercounting crime. Furthermore, the political pressures associated with being labeled a 'high-crime' city (or other jurisdiction) in the UCR lead some jurisdictions to intentionally underreport crimes or misreport their population size to the FBI in order to lower their crime rate.

In fairness to the UCR, a few crimes (homicide, auto theft, arson) are, by all indications, accurately measured by the UCR (i.e., they can be confirmed by other sources), but they are the exception to the rule, and for other crimes (e.g., rape), UCR estimates are effectively useless for estimating the incidence of the crime.

One traditional weakness of the UCR has been the failure to disaggregate crime statistics by ethnicity (e.g., arrest rates for Latinos). However, the UCR will purportedly begin collecting information on ethnicity soon, thereby allowing analysis of arrests by ethnicity.

Alternative Crime Reporting Systems

In recent years, the FBI has been developing the National Incident-Based Reporting System (NIBRS). Unlike traditional summary (i.e., aggregate) statistics available in the UCR, NIBRS provides detailed data on individual incidents of crime, making these data much more useful to researchers. Nevertheless, NIBRS data pertain only to those offenses that come to the attention of the police.

The phrase 'official statistics' is most commonly used to refer to police or UCR data on crime, but it is also used to characterize data from other governmental institutions, from federal courts to prisons to parole agencies to the US Marshals or the Drug Enforcement Agency. The Bureau of Justice Statistics (BJS), a component of the US Department of Justice, is a massive clearinghouse of data on crime and criminal justice in the United States, and its Website offers ready access to these data. The BJS also sends notifications and reports to subscribers via e-mail. Another compendium of crime and criminal justice statistics is the Sourcebook of Criminal Justice Statistics, compiled by the School of Criminal Justice at the University at Albany, and also available online. Much of the data contained in the Sourcebook are presented as time series, making them unusually helpful and valuable to investigators.

Self-Report Data

As early as the late 1940s, some criminologists were attempting to develop an alternative to the UCR for measuring crime, and the result came to be known as the self-report method (e.g., Porterfield, 1943). According to Thornberry and Krohn (2000: 34), "the development and widespread use of the self-report method of collecting data on delinquent and criminal behavior is one of the most important innovations in criminological research in the 20th century." Setting aside police reports altogether, self-report researchers confidentially interview members of a population (usually a sample) and ask them to report their own criminal or delinquent behavior during some designated period of time (usually a year). By the 1960s, the self-report survey had grown to become one of the dominant methods of measuring crime in the United States, and its adoption by researchers resulted in a number of startling discoveries. For example, the 'dark figure of crime,' or the difference between UCR figures and the true incidence of crime, turned out to be much larger than criminologists had anticipated. Additionally, among juveniles (the age-group with the highest rate of offending), violating the law proved to be group behavior in most instances rather than the action of solitary offenders. The certainty of apprehension and punishment for many crimes was also discovered to be vanishingly low, and criminologists were startled to learn that most adolescent males break the law at least occasionally. Conformity to the law, in other words, is not the rule but the exception.

As with official data, self-report research comes with its own set of issues and problems. For convenience and other reasons, most self-report surveys are conducted on juveniles, usually high school students. Self-report research on adults is rare. Ethical and legal questions are abundant in self-report research. Should investigators ever disclose the information they acquire to the police? Are respondents legally liable for the information they disclose? The accuracy of self-reports is another issue. Do respondents tell the truth? Some respondents misrepresent their behavior in long surveys because of survey fatigue – i.e., they get tired or bored of answering questions. Additionally, are respondents even able to accurately recall their behavior, and, if so, when it occurred? The more frequently individuals engage in criminal activity, the less salient any one incident will be in memory. Surprisingly enough, though, research indicates that the reliability of self-report data is high, and their validity generally falls within acceptable scientific limits when surveys are properly designed and administered (Thornberry and Krohn, 2000).

Once it arrived on the scene, self-report research quickly became the principal means in criminology for testing etiological theories of crime, because the investigator has direct access to the offender and can ask virtually any question imaginable. By contrast, police data are well removed from the offender and the event. Self-report data are also the only means for measuring the prevalence of crime, or the number of offenders in a population. Today, a number of national, longitudinal self-report studies have been funded by the federal government in the US, including the National Youth Survey, the National Longitudinal Study of Adolescent Health, and the Monitoring the Future survey. They contain what are widely considered to be the best available data on topics like drug use and adolescent sexuality.

Victimization Data

Victimization Surveys

As self-report methods were gaining ground, yet another alternative methodology for measuring crime was underway: the victimization survey (Cantor and Lynch, 2000; Mosher et al., 2011). In a victimization survey, researchers survey a population (again, usually a sample) and ask respondents to report incidents of crime committed against them or their household during a specified period of time (usually 6 months or 1 year). Following a series of pilot studies on the feasibility of such surveys, the US Department of Justice joined with the US Census Bureau in 1973 to create what is today called the National Crime Victimization Survey (NCVS), an ongoing sample survey of about 90 000 households and 160 000 individuals each year. This large sample size is necessary because some crimes are statistically rare events and require very large samples to obtain statistically reliable estimates. The NCVS measures fewer offenses than the UCR or most self-report surveys (rape and sexual assault, robbery, aggravated and simple assault, theft, household burglary, and motor vehicle theft), but its estimates of some crimes are considered to be the best available.

Victimology

The NCVS appeared at a time when criminologists were beginning to approach crime from a different perspective: the victim's perspective. This change in focus resulted in a new subfield in criminology named victimology. Rather than asking what kinds of people burgle homes, for example, victimologists ask an equally important question: What types of homes get burgled? This unique perspective generated a new body of knowledge in criminology and helped to align the field with emerging research in social science on risk and risk perception. Victimization surveys also encouraged the growth of routine activities theory, opportunity theory, and rational choice theory (Cantor and Lynch, 2000), and it fueled interest in forms of 'indirect victimization' (Conklin, 1975), that is, impacts of crime that extend beyond those who are direct victims of crime. A prime example is fear of crime, which criminologists discovered to be far more common than victimization itself, and stunning in its effects on American lifestyles (Warr, 2000). For example, a startling proportion of urban women in the United States say that they avoid going out at night or going out alone, and more than half of adult Americans say that there are places in their town they avoid. Americans worry not only about their own safety but also about the safety of others, particularly their partners and children (Warr and Ellison, 2000).

As with any source of crime data, victimization surveys have their own problems and limitations. Some crimes (e.g., so-called victimless crimes like gambling and prostitution) cannot be measured via victims. Victimization surveys can be enormously expensive (particularly, if they rely on face-to-face interviews and large geographic areas) and victim reports, as with self-reports, are susceptible to memory or recall errors on the part of respondents as well as 'telescoping' problems where respondents accurately recall events but move them backward or forward in time. These and other sources of error are relatively well understood in the NCVS, however, and the NCVS uses a sophisticated rotating panel design to 'bound' its estimates in time, as well as high-quality sampling and interview designs.

International Victimization Surveys

Today, nationwide victimization surveys are carried out in many countries. An early program was the British Crime Survey, now known as the Crime Survey for England and Wales. This survey has enhanced the field of comparative criminology and has been more amenable to innovation than its more staid ancestor, the NCVS. The International Crime Victims Survey collects data from 18 European countries with support from the United Nations and the European Commission. Among other contributions, its data on public perceptions and reactions to crime (including fear of crime) have advanced our understanding of the social impact of crime. The International Self-Report Delinquency Study is a self-report survey of seventh, eighth, and ninth graders in 31 countries (including China and Venezuela) that is administered by researchers in the School of Criminology and Criminal Justice at Northeastern University. It promises to increase our knowledge of substance abuse, delinquency, and victimization worldwide using standardized instruments and data collection procedures. Clearly, advances once limited to the United States are now spreading widely across the world.

Conclusion

As we have seen, criminologists have been innovative in devising methods for measuring crime, methods that circumvent its elusive nature. Each advance has led to major discoveries and theoretical advances. One can only imagine where the field of criminology might be if it were still confined to official data. Looking toward the future, the US Department of Justice is currently laying the foundation for a national self-report survey of rape and sexual assault, the first of its kind, and a major undertaking. The FBI continues to expand its NIBRS program, and the list of countries developing their own national victimization surveys continues to grow. These sorts of developments bode well for the future of criminology, both theoretically and methodologically.

This article has concentrated attention on the United States because self-report and victimization methodologies were initially developed there (but certainly not official statistics, which appeared in European countries as early as the nineteenth century).

Data Bases and Statistical Systems: Crime Measurement

Ronet Bachman, University of Delaware, Newark, DE, USA

Abstract

In this article, the various sources used to measure criminal victimization will be examined including police report data compiled by the Federal Bureau of Investigation, surveys conducted by the Bureau of Justice Statistics, and other surveys sponsored by the National Institute of Justice and the Centers for Disease Control and Prevention. After the basic differences across these types of data collection are examined, several crimes that are more difficult to measure will be examined including rape and sexual assault, intimate partner violence, and stalking.

Introduction

When we hear the word 'crime,' most of us think instinctively about the stereotypical stranger lurking in the dark, preparing to attack an unsuspecting victim. When we are asked, "How do we know how much crime there is?" most of us probably first think of police reports. In reality, the contextual circumstances of most crimes do not involve strangers and reports of criminal victimization to the police represent less than half of all victimizations, and for some crime, much less. In this article, you will learn how crime is measured in the United States. In addition, the measurement of several specific 'hard to measure' crimes will also be examined. By the end of the article, you will understand that the measurement of crime is a particularly difficult task, and the estimates of victimization you get are only as good as the methods used to measure them.

This article is not meant to exhaustively review all of the sources of information on crime, nor is a summation of the strengths and weaknesses of each method of collecting data provided. There are far too many data sets attempting to measure crime, each encompassing different specific collection methodologies and populations, and each with its own unique set of strengths and weaknesses. Instead, the goal is to provide a brief introduction to a few of the main sources of data on crime and to discuss some of the primary pitfalls and shortcomings commonly found in attempts to accurately identify the scope and magnitude of criminal behavior. Despite the technical nature of this article, measurement is a very important issue. The accuracy of our insights and explanations about crime is largely dependent on the quality of the information about crime that we are able to gather. Moreover, resources and strategies aimed at preventing crime and helping crime victims are also based on these estimates. Bad information can and does result in poor choices being made by policy makers, politicians, activists, and other concerned citizens. Depending on who is gathering the data and what methods they employ to get that information, the results can vary widely (Alvarez and Bachman, 2008).

Reports to Law Enforcement Officials

The most widely used source of statistical information about crime in the United States is the Uniform Crime Reporting Program (UCR), compiled by the Federal Bureau of Investigation (FBI). The UCR has collected information about criminal incidents reported to the police since 1930. The information collected by the FBI is based on the voluntary participation of state, county, and city law enforcement agencies across the United States.

For the crime of homicide, information about both the victim and the offender (e.g., the gender and race of both, the relationship between the victim and offender, the weapon used) is obtained in a separate reporting program called the Supplementary Homicide Reports. Unfortunately, such detailed information is not collected for other crimes in the UCR. To remedy this problem, in 1988, the FBI implemented a change in its collection of crime information to include more characteristics of the incident; appropriately, this is called the National Incident Based Reporting System (NIBRS). NIBRS data are more specific than the UCR and includes many more offenses that local agencies have to report information on. It includes detailed information on crime incidents, including the characteristics of the victim, such as age, gender, race, ethnicity, and resident status. In all, NIBRS categorizes each incident and arrest in one of 22 basic crime categories that span 46 separate offenses. A total of 53 data elements about the victim, property, and offender are collected under NIBRS (Mosher et al., 2002). As you can imagine, it takes a great deal of time and money to make this change and fill out this paperwork at the local police department level. Because of this time and expense, just over half of all states currently use the NIBRS format for collecting information about reported crimes while the others retain the older UCR version.

Both the UCR and the NIBRS data collection methods are problematic when estimating incidence rates of criminal victimization. It's not hard to imagine why. If victimizations are not reported to police, they are never counted in either data collection effort in the first place, and based on comparisons with national survey data, it is estimated that only about 40–50% of crimes become known to police. This is particularly problematic for certain types of violence, such as rape and violence that occurs between intimates, such as spouses and boy/girlfriends. We know that a large percentage of these victimizations are never reported to police. In sum, there is a great deal of evidence documenting the large gap between the true extent of victimization and offending and the amount of crime known to police. The major sources of this gap, according

 http://dx.doi.org/10.1016/B978-0-08-097086-8.45055-5

to Clayton Mosher, and his colleagues (Mosher et al., 2002) are the following: the inability of police to observe all criminal activity, the reluctance of crime victims and witnesses to report crime to the police, and variation in the recording of 'known' crime incidents because of police discretion.

Because of this weakness in police reports, random sample surveys of the population are often used as the social science tool of choice for uncovering more accurate information about criminal victimization. However, as can be imagined, surveys employing diverse methodologies and different definitions of violence have resulted in tremendously diverse estimates. Taking violence against women as an example, survey estimates of how many women experience violence from an intimate partner annually range from 9.3 per 1000 women to 116 per 1000 women (Bachman, 2000). This is a huge range. Further, the methodological differences across survey methodologies often preclude direct comparisons across studies.

The measurement of specific crimes will be reviewed in subsequent sections. Here we will briefly summarize to types of surveys that are designed to more accurately measure crime victimization. The first is the only national ongoing survey that tracks criminal victimization over time. It is sponsored by the Bureau of Justice Statistics of the U.S. Department of Justice and is called the National Crime Victimization Survey (NCVS). Instead of focusing on victimizations, the second survey we will discuss was designed to measure the offending behavior of adolescents and is called the National Youth Survey (NYS).

The NCVS annually interviews over 100 000 individuals of 12 years of age or older and is the second largest ongoing survey sponsored by the U.S. Government. It measures both nonlethal violent and property crime victimizations. In addition, identity theft has also been added to the list of crimes covered by the NCVS along with other questions that are asked on various supplemental surveys periodically. Excluding the identity theft screening questions, the NCVS currently uses the screening questions listed in **Table 1**.

As you can see from **Table 1**, the screening questions rely on behavior-specific wording instead of asking directly about victimizations using crime jargon such as "have you ever been robbed?" (Bureau of Justice Statistics, 2013). This is important. A great deal of research has demonstrated that asking questions using behavior-based wording instead of legally based phrases uncovers a significantly greater number of victimizations, particularly when victims may not self-identify themselves as crime victims. As you might imagine, asking people about their experiences in these numerous behavior-specific ways and with many cues for types of offenders (e.g., a stranger or someone you know well) and types of locations (e.g., in a vacation home, in a laundry room) uncovers many more victimizations than those reported to police.

These types of victimization surveys give us much more accurate estimates of crime victimization, but who is most likely to commit crime? Relying on police reports to estimate characteristics of offenders involves the same problems as using these data to estimate who is most likely to be victimized. Are offenders who are arrested for violent offending actually representative of all offenders? The quick answer is no. Not surprisingly, early self-report surveys of offending behavior in the 1940s revealed that a relatively large number of committed offenses were undetected by the police. Although police report data at the time indicated offenders were more likely to be minorities from low socioeconomic backgrounds, self-report data revealed that a great number of offenses were being reported by people from relatively privileged backgrounds. As you might guess, these offenses rarely came to the attention of the police, and when they did, they rarely resulted in an arrest (Short and Nye, 1958). Based on these early studies, researchers interested in offending behavior – like those interested in victimization – began to rely on survey methodology instead of police reports. That trend continues to this day.

One of the most thorough contemporary surveys of offending behavior is the NYS, which was first collected in 1976 from a national probability sample of 11- to 17-year-olds. These youth were interviewed many times during the following years, with the last interview data collected in 1995, although there are similar surveys that have taken its place. **Table 2** displays some of the questions used to measure the violent offending behavior in the NYS. As you can see, here too researchers have used behavior-specific wording instead of relying on the use of crime categories and labels.

Rape and Sexual Assault

Like all victimizations, estimates of rape and sexual assault victimization can be obtained from several different sources. The important question remains, however, which is the most accurate? Recall that the FBI's UCR and its NIBRS include only those victimizations that the police find out about, either through the victim or someone else. Because rape and sexual assaults remain the least likely forms of violence to be reported to police, our best estimates about how many victimizations there are, and who is most likely to be victimized and by whom, remain problematic. The most reliable information on rape victimization – imperfect and incomplete as it is – comprises the data obtained from social scientific surveys.

Even surveys, however, can have results that vary widely depending on how the questions are worded, the composition of the sample obtained, and the context of the survey. The only survey that monitors rape and sexual assault on an annual basis is the NCVS. However, as presented in **Table 1**, the questions used to uncover rape are probably the least behaviorally specific compared to the other national surveys that have been conducted. The questions used for the NCVS (**Table 1**) are vague and these broad questions lend themselves to different types of interpretations. Perhaps the perpetrator was an acquaintance or even a husband, and the victim may therefore not define it as rape even though it is considered as such by all state legal statutes. Or perhaps there was no overt use of force, so the victim may not define it as an 'attack.' The word rape itself has a variety of meanings that are used differently depending upon the situation and the individuals involved. Because of this, these types of questions about rape are prone to a great deal of underreporting. In

Table 1 Screening questions used for the National Crime Victimization Survey (excluding identity theft questions)

1. I am going to read you some examples that will give you an idea of the kinds of crimes this study covers. As I go through them, tell me if any of these happened to you in the last 6 months.
   Was something belonging to YOU stolen, such as
   a. things you carry, like luggage, a wallet, purse, briefcase, book?
   b. clothing, jewelry, or cell phone?
   c. bicycle or sports equipment?
   d. things in your home – like a TV, stereo, or tools?
   e. things outside your home such as a garden hose or lawn furniture?
   f. things belonging to children in the household?
   g. things from a vehicle, such as a package, groceries, camera, or CDs?
   Did anyone ATTEMPT to steal anything belonging to you?
2. Other than any incidents already mentioned, has anyone
   a. broken in or ATTEMPTED to break into your home by forcing a door or window, pushing past someone, jimmying a lock, cutting a screen, or entering through an open door or window?
   b. illegally gotten in or tried to get into a garage, shed, or storage room?
   c. illegally gotten in or tried to get into a hotel or motel room or vacation home where you were staying?
3. If respondent has vehicle(s) during the last 6 months,
   a. was the vehicle(s) stolen or used without permission?
   b. Did anyone steal any parts such as a tire, car stereo, hubcap, or battery?
   c. Did anyone steal any gas?
   d. Did anyone ATTEMPT to steal any vehicle or parts attached to it/them?
4. Were you attacked or threatened OR did you have something stolen from you
   a. at home including the porch or yard?
   b. at or near a friend's, relative's, or neighbor's home?
   c. at work or school?
   d. in places such as a storage shed or laundry room, a shopping mall, restaurant, bank, or airport?
   e. while riding in any vehicle?
   f. on the street or in a parking lot?
   g. at such places as a party, theater, gym, picnic area, bowling lanes, or while fishing or hunting?
   Did anyone ATTEMPT to attack or ATTEMPT to steal anything belonging to you from any of these places?
5. Other than any incidents already mentioned, has anyone attacked or threatened you
   a. with any weapon, for instance, a gun or knife?
   b. with anything like a baseball bat, frying pan, scissors, or a stick?
   c. by throwing something, such as a rock or bottle?
   d. by grabbing, punching, or choking?
   e. by raping, attempted rape or other type of sexual attack?
   f. by face-to-face threats?
   g. attacking, threatening, or using force by anyone at all?
   Please mention it even if you are not certain it was a crime.
6. People often do not think of incidents committed by someone they know. Did you have something stolen from you OR were you attacked or threatened by
   a. someone at work or school?
   b. a neighbor or friend?
   c. a relative or family member?
   d. any other person you have met or known?
7. Incidents involving forced or unwanted sexual acts are often difficult to talk about. Have you been forced or coerced to engage in unwanted sexual activity by
   a. someone you did not know before?
   b. a casual acquaintance?
   c. someone you know well?

If respondents reply affirmative to one of these latter questions, interviewers next ask *Do you mean forced or coerced sexual intercourse?* to determine whether the incident should be recorded as rape or as another type of sexual attack.

8. During the last 6 months, did you call the police to report something that happened to you which you thought was a crime?

order to avoid this problem, some researchers contend that respondents need to be asked more behaviorally specific questions to uncover rape victimizations that may have occurred. Beginning with a study by Koss, Gydycz and Wisniewski (1987) that examined the rape victimization experiences of college women, most recent surveys attempting to estimate the magnitude of rape have used very specific question wording. For example, the National Violence Against Women and Men Surveys (NVAWMS) asked the questions displayed in **Table 3**. The National Intimate Partner and Sexual Violence Survey (NISVS) conducted by the Centers for Disease Control used these same questions, and further cued respondents to think of unwanted sex that occurred when they were "unable to consent to it or stop it from happening because they were drunk, high, drugged, or passed out from alcohol, drugs, or medications." (Black et al., 2011).

Table 2 Screening questions used by the NYS to uncover self-reported offending

(Introduction) This section deals with our own behavior. I would like to remind you that all your answers are confidential. I will read a series of behaviors to you. Please give me your best estimate of the exact number of times[a] you have done each thing during the last year from Christmas a year ago to the Christmas just past.

1. Carried a hidden weapon other than a plain pocket knife
2. Attacked someone with the idea of seriously hurting or killing him or her
3. Been involved in gang fights
4. Tried to take something from someone with the use of force or with the threat of force

[a]Note: Response options were (1) once a month, (2) once every 2–3 weeks, (3) once a week, (4) two to three times a week, (5) once a day, and (6) two to three times a day. NYS, National Youth Survey.

Table 3 Questions used in the National Violence Against Women and Men Surveys to uncover incidents of rape and sexual assault

- (For female respondents) (1) Has a man or boy ever made you have sex by using force or threatening to harm you or someone close to you? Just so there is no mistake by sex we mean putting a penis in your vagina.
- (The remaining questions are for all respondents) (2) Has anyone, male or female, ever made you have oral sex by using force or threat of force? Just so there is no mistake, by oral sex we mean that a man or boy put his penis in your mouth or someone, male or female, penetrated your vagina or anus with their mouth.
- (3) Has anyone ever made you have anal sex by using force or threat of harm? Just so there is no mistake, by anal sex we mean that a man or boy put his penis in your anus.
- (4) Has anyone, male or female, ever put fingers or objects in your vagina or anus against your will or by using force or threats?
- (5) Has anyone, male or female, ever attempted to make you have vaginal, oral, or anal sex against your will, but intercourse or penetration did not occur?

Importantly, each of the acts described in Table 3 represent an element that constitutes rape in all states as well as federal crime statutes. As with the NCVS, both males and females can be either perpetrators or victims of rape. Asking about each of these acts separately cues respondents to think about all of the events that have happened to them that they may not have considered with the broad question used by the NCVS. In addition, there are other reasons why estimates differ. The context in which the survey is introduced to respondents, along with other factors, also affects how many rapes the survey uncovers. For example, the NVAWMS is introduced to respondents as a survey about issues of safety, unlike the NCVS, which is introduced to respondents as a survey interested in crime. These differences may also affect the estimates obtained. According to the NCVS, the rate of rape has not changed much over time, with approximately 250 000 people of 12 years of age and older becoming the victims of rape annually. The majority of rape victimizations reported to NCVS interviewers were never reported to police. In fact, fewer than 3 in 10 rape and sexual assault victimizations, according to the NCVS, are ever reported to police. The NVAWMS, on the other hand, estimates that over 900 000 men and women over 18 years of age become the victims of rape annually. This is far more than the number estimated by the NCVS. Clearly, the way in which you ask people about the victimization experiences affects the magnitude of estimates obtained by surveys.

Unfortunately, the only estimates of rape and sexual assault available at most local levels, including state and city levels, are from the less reliable police reports. It is very expensive to conduct a survey that is representative of any given population, and most local governments do not have the ability to fund such an endeavor. Unfortunately, we know victims are reluctant to report to police for many reasons, including the personal nature of the victimization, fear of retaliation from the offender, and the treatment they expect to receive from the media and the criminal justice system. Additionally, many victims often believe that they will not be believed by the police if they report the rape, and many also suffer a sense of shame about their victimization (Holmes and Holmes, 2002). It is a sad reality that rape victims still suffer from many stereotypes, misperceptions, and the social stigma and embarrassment associated with this crime.

Intimate Partner Violence

Similar to rape and sexual assault, determining the true magnitude of assaults between intimate partners such as spouses/exspouses, and boy/girlfriends, and exes, has been difficult. While this type of violence also includes verbal and controlling behaviors, this article will focus on measuring the physical nature of the crime. The Centers for Disease Control and Prevention (CDC) have provided a very useful definition when describing intimate partner violence (IPV):

> The intentional use of physical force with the potential for causing death, disability, injury, or harm. Physical violence includes, but is not limited to, scratching; pushing; shoving; throwing; grabbing; biting; choking; shaking; slapping; punching; burning; use of a weapon; and use of restraints or one's body, size, or strength against another person.
>
> CDC, 2013

Of course, we know IPV has been around forever, even though it has only been in the past 30 years that it has finally been acknowledged as a social problem. As recently as the 1970s and into the 1980s, police rarely made arrests when they were called to the scene of an intimate partner assault because it was thought to be a 'private matter' that was not the concern of the criminal justice system. The law, it seemed, did not extend past the front door. Widespread beliefs about the nature of the family and of gender roles contributed to this lack of attention. Fortunately, attitudes and policies have changed – largely as a result of the activism of various victims' and women's rights groups. Today, violence that goes on behind closed doors between intimates is usually treated like any other type of violence, with arrest being the norm rather than the exception. Because IPV is usually more private and hidden than some other forms of violence, its detection and intervention remain somewhat problematic, as does our ability to measure its perpetration.

Similar to the issues that plague measuring rape victimizations, surveys using diverse methodologies and different definitions of IPV have resulted in tremendously dissimilar estimates. For example, estimates of how many women experience violence by an intimate partner annually range from 9.3 per 1000 women to 116 per 1000 women. Furthermore, the differences across survey methodologies often preclude direct comparison across studies. There have been only four large nationally representative surveys that have estimated the annual rates of IPV: the National Family Violence Survey (NFVS), the NCVS, the NVAWMS, the National Intimate Partner and Sexual Violence Survey (NSVIS). Because of their procedural differences, each of these surveys has resulted in quite different estimates of IPV. While most researchers are familiar with the methodological differences between surveys, few policy makers take these into account when making generalizations about how often IPV takes place. This has unfortunately led to widespread confusion and controversy.

The NFVS was the first national survey devoted exclusively to estimating incidents of IPV. Its sample included only married or cohabiting couples and measured violence using an instrument called the Conflict Tactics Scale (CTS) (Straus and Gelles, 1990). The introduction to the CTS asks respondents to "think of situations in the past year when they had a disagreement or were angry with a specified family member (husband, child, etc.)" and to indicate how often they engaged in each of the acts included in the CTS. The list of acts covered in the CTS spans a range of behaviors, including reasoning, verbal aggression, and physical aggression or violence. Physical violence by the CTS index is often subdivided into two categories: minor violence and severe violence. These categories consist of the following acts: *Minor violence*: (1) threw something, (2) pushed, grabbed, or shoved, (3) slapped; *Severe violence*: (1) kicked, bit, or hit with a fist, (2) hit or tried to hit with something, (3) beat up, (4) choked, (5) threatened with a knife or gun, (6) used a knife or fired a gun.

Estimates from the 1985 NFVS indicate that about 11.6% of couples had experienced some type of assault in the previous 12 months. Extrapolated to the total married population, this survey estimates that almost one out of eight husbands carried out one or more violent acts during the year of this study. Further, the rate of severe violence perpetrated by husbands indicates that about 1.8 million women were beaten by their partner that year. The NFVS also estimates that rates of violence perpetrated by wives against husbands are very similar to rates of violence perpetrated by husbands against wives. Herein lies one of the most frequent criticisms of the CTS methodology: that it measures acts of violence in isolation from the circumstances under which the acts were committed. As critics point out, for example, it ignores who initiates the violence, the relative size and strength of the persons involved, and the nature of the participants' relationship (DeKeseredy and Schwartz, 2011). It should be noted here that a new version of the CTS called the CTS2 has been developed to address some of the methodological deficiencies of the original scale, but the new version still does not allow a researcher to account for the sequence of events that precipitated an act of violence. Thus acts of aggressive violence can still not be separated from those assaults that were used in self-defense.

As we noted earlier (**Table 1**), the NCVS asks a number of questions cueing respondents to think of many different kinds of attacks (e.g., with anything like a baseball bat, frying pan, scissors, or a stick), and different types of offenders (e.g., strangers, someone you know well), but it does not ask directly about attacks from intimate partners or other family members. Estimates of IPV from the NCVS indicate that in 2010, the rate of IPV against females was 5.9 per 1000 compared to a rate of only 1.1 for males. This translates into nearly 1 million females of 12 years of age and over being violently attacked by their intimate partners annually, which does not include homicides. Also notice that, unlike the NFVS, the NCVS finds that females have much higher rates of IPV victimization compared with males, which is consistent with homicide data.

The NVAWMS was a nationally representative survey that was introduced to respondents as a survey on personal safety (noted above), and measured assault by using a modified version of the CTS (Tjaden and Thoennes, 2000). Respondents included women and men of 18 years of age and older; they were asked about assaults, which had occurred as children and as adults using the following screening questions:

Not counting any incidents you have already mentioned, after you became an adult did any other adult, male or female ever ...

1. Throw something at you that could hurt?
2. Push, grab or shove you?
3. Pull your hair?
4. Slap or hit you?
5. Kick or bite you?
6. Choke or attempt to drown you?
7. Hit you with some object?
8. Beat you up?
9. Threaten you with a gun?
10. Threaten you with a knife or other weapon?
11. Use a gun on you?
12. Use a knife or other weapon on you?

The NVAWMS obtained higher estimates than the NCVS but lower estimates than the NFVS: 1.3% of women and 0.9% of men reported being assaulted by their intimate partners annually. Importantly, this survey also examined how many women and men experienced violent attacks over the course of their adult lives. Over one in five women (22%) and 7.4% of men had been assaulted by an intimate partner in their lifetimes.

The most recent survey conducted to measure IPV was conducted by the CDC in 2010 and is known as the NISVS. Like the NVAWMS, the NISVS not only asked respondents about victimizations that happened to them in the past 12 months but also about victimizations they had experienced in their lifetimes. And like the NVAWMS, the survey also measured a representative sample of the adult men and women of 18 years of age and older. In addition to questions about coercive control (e.g., tried to keep you from seeing or talking to your family or friends, kept track of you by demanding to know where you were and what you were doing), which are often behaviors that precede physical violence in relationships, the physical violence questions included those from above,

with the addition of "slammed you against something," "burned you on purpose," and "hurt you by pulling your hair." Another addition was that respondents were specifically asked about all intimate partners including same-sex couples. Both the NVAWMS and the NCVS collect data on same-sex couple violence, but do not directly ask respondents their sexual orientation. As such, it is only illuminate when the gender of both the victim and the perpetrator are examined in combination. Estimates from the NISVS reveal that about 4% of women and 4.7% of men had experienced a physical attack by an intimate partner in 2010. However, women were more likely than men to be victimized by severe acts of physical violence, which did not include slapping, pushing, or shoving (Black et al., 2011).

As you can clearly see, the ways in which people are asked about their victimization experiences significantly impact the number of people estimated to have experienced a victimization. Unfortunately, policy makers and researchers alike rely on published estimates of violent victimization from one or more of the surveys without recognizing or understanding the limitations of each. When you ask, "How many men and women are assaulted by their intimate partners each year?" the answer you get depends on which survey you rely on. Is it possible to compare incident rates across surveys? The simple answer is no. Because of the methodological differences between the different surveys, comparisons of their different estimates of IPV are not valid. How accurate can it really be to compare information from the NFVS, which interviewed only married and cohabiting couples, with estimates generated from the NCVS and NVAWMS that relied on national probability of samples of men and women in general, regardless of marital status? However, when the NCVS and the NVAWMS data are restricted to a similar context (i.e., adult victimizations involving lone offenders), research indicates that estimates of IPV still remain higher from the NVAWMS and the NISVS compared with the NCVS. This is undoubtedly due to the more specific screening questions used by the NVAWMS and also the specific questions about acts perpetrated by husbands, boyfriends, and former intimates (Bachman, 2000). In sum, when you are asked how many men and women experience IPV, your answer should be, "That depends on the methodology used to obtain the estimates." Regardless of which data set you rely on, however, all estimates that IPV is a significant problem. For all too many women, their partner poses more of a risk for serious harm and death than a stranger on the street.

Stalking

Before the measurement of stalking is discussed, the conceptualization of stalking should first be addressed. Does stalking involve unwanted repeated attempts at contact or only unwanted repeated attempts at contact that make someone feel fear? If we feel fear, how much fear is necessary for an act of stalking to be considered a crime? A 'great deal of fear' or just 'some fear?' The NISVS used the following definition of stalking:

> Stalking victimization involves a pattern of harassing or threatening tactics used by a perpetrator that is both unwanted and causes fear or safety concerns in the victim. … a person was considered a stalking victim if they experienced multiple stalking tactics or a single stalking tactics multiple times by the same perpetrator and felt very fearful, or believed that they or someone close to them would be harmed or killed as a result of the perpetrator's behavior.
>
> Black et al., 2011

The tactics measured included unwanted phone calls, text messages or hang-ups, unwanted e-mails or messages through social media, unwanted mail or presents, unwanted following from a distance or through the use of devices, such as GPS systems, showing up at the victim's home or workplace, leaving items for victim to find, or doing things that indicate the stalker had been in the victim's home or car.

In 2010, the NISVS found that about 16% of women had been stalked at some point in their lifetimes and 4% had been stalked in the 12 months prior to the survey. The incidents for men was much lower, with about 5% of men experiencing stalking in their lifetimes and just over 1% experiencing it in the past 12 months. For lifetime reports of stalking, the majority of female victims (66%) were stalked by intimate partners, while the male victims were equally likely to be stalked by intimate partners and friend/acquaintances (41 and 40% respectively). The NCVS also conducted a special Supplemental Victimization Survey in 2006 that measured stalking. It found that 2.2% of females of 18 years of age and older compared to 0.8% of their male counterparts had experienced stalking in the past 12 months. Together, it was estimated that over 3 300 000 stalking victimizations occurred annually. These victimization data conform to perpetration statistics, since research indicates that the vast majority of perpetrators are men (Tjaden and Thoennes, 2002).

Conclusion

This article has illustrated that measuring the true magnitude of criminal victimization is not as easy as it sounds. Relying on police report data compiled by the UCR or the NIBRS by the FBI only a tip of the ice burg of victimization. Random sample surveys of the population more accurately measure the victimizations that remain hidden from police detection because of nonreporting, however, even they have measurement error. When a newspaper or news program reports that crime is going up or down in the nation or in various locations, it is important to ask where these numbers came from and how victimization was measured. Of course, this question should also be asked whenever we are provided 'facts' about criminal victimization.

Data Bases and Statistical Systems: Culture

Gunnar Otte and David Binder, Institute of Sociology, Johannes Gutenberg University Mainz, Mainz, Germany

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The measurement of culture in statistical systems is a rather new endeavor. In international comparison, considerable differences exist in classifications and indicators. This article provides an overview of definitional and classificatory approaches as well as transnational attempts of harmonizing cultural statistics. In particular, statistical systems and databases are introduced with regard to the cultural industries, artists, and cultural producers, organizations responsible for the dissemination of culture, and consumers and recipients of culture.

Introduction

'Culture' is one of the most ambiguous terms in the social sciences. Currently, there are at least six scientific usages of the word:

- Culture as everything created by humankind (as opposed to 'nature').
- The anthropological notion of culture as the social organization of whole societies.
- Cultures as historical lineages of world civilizations (e.g., 'Western culture').
- Culture as the value system of a society, group, or individual (e.g., 'postmaterialism').
- Culture as the lifestyle of a society, group, or individual, i.e., a set of typical everyday life practices (e.g., 'hedonistic' or 'sustainable lifestyles').
- Culture in terms of arts.

It is beyond the scope of this article to discuss statistical systems for all these notions of culture – if they exist at all. In particular, we will not address conceptions of measuring religious beliefs, cultural values, language systems, ethnicity, and lifestyles. Rather, we focus on frameworks originating from the arts in a wider sense.

After devoting some more words on definitional issues in Section Defining Culture, we introduce the most important classifications of culture that are used in statistical systems (Section Classifying Culture). Besides, two transnational conceptions of cultural statistics – as proposed by the UNESCO and the European Union (EU) – are presented (Section Cultural Statistics in Transnational Perspective). In Section Cultural Industries, we take up the much debated question of how to delineate the cultural and creative industries. We then follow a process model of cultural products, ranging from their creation and production via their dissemination to their consumption and reception. Specifically, we discuss the problem of the inclusion coverage of artists (Section Artists and Producers of Culture), present research on the organization-based dissemination of culture (Section Dissemination of Culture), and summarize the methodology of cultural participation surveys (Section Consumption and Reception of Culture).

Defining Culture

There is little agreement on definitional issues in statistical systems of culture. What belongs to the 'cultural domain' is often decided ad hoc and on the basis of available databases. Some recent statistical reports refer to the UNESCO universal declaration on cultural diversity, which defines culture as the "set of distinctive spiritual, material, intellectual and emotional features of society or a social group" that "encompasses, in addition to art and literature, lifestyles, ways of living together, value systems, traditions and beliefs" (UNESCO, 2001). Taking up value systems and lifestyles, this definition is considerably broader than arts-centered approaches. When it comes to operationalizing 'culture' in statistical systems, however, the domains and indicators selected refer rather loosely to this definition; 'pragmatic' considerations prevail (UNESCO-UIS, 2009: 22f.). While many dimensions of values and lifestyles are disregarded by official statistics, the arts are either part of most frameworks or even constitute their main focus.

It therefore seems appropriate to engage in definitions of 'the arts.' To begin with, the arts are the social system that is centered around 'works of art.' They can be considered 'products,' comprising (tangible) goods and (intangible) services. Such products vary tremendously in form and content and therefore works of art are hard to determine according to innate characteristics. However, they can be defined by reference to the processes of their production or reception. Reception-based definitions consider a product as a 'work of art' if actors in the art system ascribe this label to it, drawing on quality or beauty criteria. The problem is that value judgments vary historically, spatially, and interindividually among actors and that other products – such as cars – can be judged by aesthetic criteria as well. Production-based definitions avoid these difficulties. They regard products as 'art' if their production is guided primarily by the objectives of aesthetic expression. Although important aesthetic components can be found in automobile production, functional–technical imperatives like roadworthiness, safety, and energy consumption dominate the development of cars. Therefore, they do not constitute artworks. However, children's drawings are primarily aesthetic expressions as well. To exclude such cases, the definition should be restricted to professional producers or artists. An 'artist' is somebody who sends

professional behavioral signals toward the art system, for example, by taking part in contests, becoming a member of professional organizations, or offering his or her artistic products for money (Throsby, 2001). In summary, works of art are all products of primarily aesthetic expression that are produced by artists in their professional practice.

This definition does not restrict artworks and artists to those accepted by art critics, but includes products and producers devalued or ignored by them. It implies treating 'high culture' as well as 'popular,' 'mass,' and 'folk culture' as objects of investigation. Although our definition is rather wide, there are boundary zones of products whose status as art or nonart is unclear, especially in the applied arts (e.g., crafts, architecture, design, advertisement) and in popular entertainment (e.g., vaudeville, circus). Models of concentric circles or core–periphery gradings provide a solution: They treat genuinely artistic products and occupations as the center, or core, of the art system and locate ambiguous products and partially artistic occupations in the fringe, or periphery, of a wider creative sphere (KEA, 2006: 53ff.; Throsby, 2008a).

In the debate on the economic impact of culture, the 'cultural industries' are usually considered a subset of the 'creative industries.' While the former contain artistic core industries like music, film, the visual and performing arts, publishing, and broadcasting, the latter may encompass the advertisement or software industries. For instance, the UK *Creative Industries Mapping Document* defines the 'creative industries' as "those industries which have their origin in individual creativity, skill and talent and which have a potential for wealth and job creation through the generation and exploitation of intellectual property" (DCMS, 2001: 5). Again, the notion of 'creativity' is used rather heterogeneously in this debate. It deviates from the use in psychology, where creativity is understood as "the ability to produce work that is both novel (i.e., original, unexpected) and appropriate (i.e., useful, adaptive concerning task constraints)" (Sternberg and Lubart, 1999: 3). In accordance with this, creativity is likely to be found from the arts and sciences to craftwork and manufacturing and cannot be confined to a specific industry.

Classifying Culture

Process Models of Culture

Definitional difficulties notwithstanding useful models and classifications of culture have been developed. In the sociology of the arts, a process model of cultural products is widely used (Alexander, 2003). In **Figure 1**, a simple three-stage model is presented. It starts with the assumption that cultural producers develop creative ideas and transform them into cultural products. In modern societies, these products are rarely brought to consumers directly, but are evaluated and disseminated by intermediate actors. They are performed or exhibited in concert halls and galleries; distributed by publishing houses and labels; traded via wholesale, retail, and Internet platforms; popularized on television and radio, in magazines and newspapers; filtered and reviewed by critics; archived and preserved; and sometimes canonized in educational curricula and cultural histories. Because of this complex preselection process, cultural products have unequal chances of reaching consumers and being successful. On the demand side, the model distinguishes the processes of 'consumption' in terms of quantitative demand and 'reception' in terms of subjective acquisition. It is worth noting that consumers, or recipients, are to a significant degree amateur artists themselves, when playing instruments, making pottery, painting, and so on. Sometimes process models are presented as a 'cultural cycle' indicating that the creation and production of particular types of products are stimulated by market demand (UNESCO-UIS, 2009: 19f.). We allow for this proposition by the feedback loop in the figure. From an economic perspective, process models of cultural content are often interpretated as production chains with several value-adding stages.

Another model, the three-sector model, also starts with the creative professional, but positions him or her relative to three cultural subsectors that serve as organizational and financial bases of cultural production: the private sector (economy), the public sector (state), and the intermediate sector of nonprofit organizations (civil society). This differentiation is used in some mapping studies of the creative industries, for example, in Switzerland (Weckerle et al., 2008). There is a tendency to confine the creative industries to the private, for-profit sector.

Models of Cultural Industries

A long-standing concern is the classification of the cultural industries. Based on the assumption that cultural products have an economic and a cultural value, Throsby (2008a) proposes a concentric circles model with four layers of cultural industries. The cultural content of their products decreases, relative to their economic value, from the inner to the outer circles. In the center are the 'core creative arts' (literature, music, performing arts, visual arts), followed by 'other core cultural industries' (film, museums/galleries/libraries, photography), the 'wider cultural industries' (heritage services, publishing and print media, sound recording, television and radio, video and

Figure 1 Process model of cultural products.

computer games) and, in the outer circle, 'related industries' (advertising, architecture, design, fashion) (Figure 2). Importantly, Throsby validates his model by classifying single occupations as creative or noncreative and by calculating, for the four layers, the proportion of total industry employment in creative personnel. Using a similar model, the consultancy KEA European Affairs (2006: 56) comes up with a partly different proposal. Because the 'core arts field' is defined by nonindustrial activities whose output are prototypes, it is restricted to the visual and performing arts (including crafts) as well as cultural heritage. Music and literature, together with film, video, television, radio, video games, and publishing, are assigned to the next layer, the 'cultural industries.' They are assumed to be organized around activities aimed at massive reproduction. Obviously, definitional intricacies and decisions on aggregation levels – Throsby separates musical and literary creation from the industries reproducing these works – easily amount to different classification schemas.

Cultural Divisions by Genre

Not only should cultural content be sorted according to product groups and industries, such as 'music,' 'film,' and so forth. It can also be grouped across such divisions. In a major work in Germany, Schulze (1992) identified three 'aesthetic everyday life schemes' that are central for structuring individual tastes. Every consumer exhibits a specific mixture of proximity and distance toward these schemes. The 'high culture scheme' comprises refined products suited for 'contemplation' and an 'antibarbarian' distinction (e.g., classical music, serious literature, museums); the 'trivial culture scheme' includes folk culture and light entertainment emanating 'harmony' and enabling an 'anti-eccentric' distinction (e.g., easy listening, quiz shows, light novels); the 'action culture scheme' includes pop and youth cultural products fit for 'action' and 'anticonventional' distinction (e.g., rock music, science fiction, bars, and clubs). These schemes have shown to be quite stable over time and correlate strongly with age and education. In order to map the schemes, cultural objects have to be classified into artistic genres or stylistic ages. This is rather easy in the domains of music and film, but more difficult in the visual arts, literature, and theater. Moreover, genre classifications have to be adapted to regional cultural traditions.

Figure 2 Concentric circles model of cultural industries. Model adapted from Throsby, D., 2008a. The concentric circles model of the cultural industries. Cultural Trends 17, 150.

Cultural Statistics in Transnational Perspective

UNESCO Framework for Cultural Statistics

On the transnational level, two efforts of developing a coherent framework for cultural statistics are particularly worth noting: those of the UNESCO and the EU. Both are meant as tools for organizing cultural statistics in an internationally comparable manner.

After the first initiatives in 1972, it took until 1986 for the first UNESCO *Framework for Cultural Statistics* (FCS) to be enacted (UNESCO, 1986). The central instrument is a set of matrices crossing 10 cultural 'categories' and several subcategories, i.e., product and activity groups in the rows with five cultural 'functions' (taken from a process model like in Figure 1) in the columns. For each cell, quantitative indicators are specified. The framework goes far beyond the arts, as defined above, by taking up cultural heritage, media systems, sports and games, aspects of family, community and organizational life as well as quality of life in the natural and urban environment.

In 2009, the FCS was updated considerably (UNESCO-UIS, 2009). The totality of what is delineated as 'culture' has been enlarged (with design, architecture, advertising, Internet services, and tourism) and the former 'categories' have been regrouped into six 'cultural domains':

- Cultural and natural heritage (museums; archeological and historical places; cultural landscapes; natural heritage)
- Performance and celebration (performing arts; music; festivals, fairs, and feasts)
- Visual arts and crafts (fine arts; photography; crafts)
- Books and press (books; newspaper and magazines; other printed matter; library; book fairs)
- Audiovisual and interactive media (film and video; television and radio; Internet podcasting; video games)
- Design and creative services (fashion, graphic, interior and landscape design; architectural services; advertising services).

Outside of these genuinely cultural domains, two 'related domains' are added:

- Tourism (charter travel and tourist services, hospitality and accommodation)
- Sports and recreation (sports, physical fitness and well-being, amusement and theme parks, gambling).

Linked to each of the above domains are four 'transversal domains,' the first one being considered entirely cultural, the last three partially cultural:

- Intangible cultural heritage (oral traditions and expressions, rituals, languages, social practices)

- Education and training (with regard to cultural values and skills)
- Archiving and preservation
- Equipment and supporting materials.

It is worthy of mention that the current FCS takes up the matrix approach cross-tabulating cultural domains and a five-stage process model – creation, production, dissemination/transmission, exhibition/reception, consumption/participation – but abstains from specifying indicators.

EU Statistical System of Culture

In the EU, an important step toward a statistical system of culture was made by the *Leadership Group on Cultural Statistics* from 1997 to 2000. Its work was taken up by the Statistical Office of the EU (Eurostat, 2011) and the *European Statistical System Network on Culture*, collaborating from 2009 to 2011 (ESSnet-Culture, 2012). For ESSnet-Culture, the conceptual starting point is the notion of 'cultural activities,' i.e., the processing of goods and services whose 'intrinsic or symbolic value' surmounts their 'technical value.' Professionals and amateurs exercise these activities – for-profit or not-for-profit – with regard to specific cultural domains and cultural functions. A 'cultural domain' is defined as "a set of practices, activities or cultural products centred around a group of expressions recognized as artistic ones" (ESSnet-Culture, 2012: 55). Ten equally ranking domains are distinguished:

- Heritage (museums, historical places, archaeological sites, intangible heritage)
- Archives
- Libraries
- Book and press
- Visual arts (plastic and fine arts, photography, design)
- Performing arts (music, dance, drama, circus, cabaret, combined arts, and other live shows)
- Audiovisual and multimedia (film, radio, television, video, sound recordings, multimedia works, video games)
- Architecture
- Advertising
- Art crafts.

Because 'artistic creation' is at the core of the framework, architecture, advertising, and art crafts are included only in their cultural components (e.g., architectural design, but not construction). Explicitly excluded are general system and applications software; information and telecommunication; leisure, entertainment, and tourism; natural reserves, zoos, and botanical gardens; and manufacturing of ornamental products.

Cutting across the domains, six sequenced 'functions' are distinguished: creation (original work), production and publishing, dissemination and trade, preservation, education, and management and regulation. Instead of using a full process model that includes the demand side, ESSnet-Culture builds a third axis into its framework by proposing four 'dimensions' that constitute important research foci. Each of the domain-by-function intersections, i.e., cultural activities or products, is viewed with regard to (1) the employment it entails, (2) the public financing it presupposes, (3) the private consumption it stimulates, and (4) the social participation it generates.

As the 2009 FCS is taken into account by ESSnet-Culture, important similarities appear: The cultural domains overlap to a large extent and the matrix crossing domains and functions is the central organizing tool for sorting statistical indicators. There are also deviations, however. The boundaries of the cultural sector are more restricted in the EU approach: Natural heritage, crafts in general, software industries, tourism, sports, and recreation are not included. The FCS 'transversal domains' are either ranked under 'heritage' (intangible cultural heritage), treated as a cultural domain (archiving), shifted to a function (education and training) or considered a 'related activity' outside the cultural sector (equipment and support). In addition, four 'dimensions' are specified as main research objectives. It should be noted that both frameworks are grounded less in theoretical terms than the concentric circles models by Throsby (2008a) and KEA European Affairs (2006).

Cultural Industries

Since national and local governments strongly discovered the economic impact of the cultural, or creative, industries around the turn of the millennium, fueled by the UK *Creative Industries Mapping Document* (DCMS, 2001) and Richard Florida's (2002) widely recognized book on the 'creative class,' reports on the cultural industries flourish on a worldwide scale (for an overview, see UNESCO-UIS, 2012). The main impetus is to quantify the cultural industries, in comparison with other industries, in terms of structure and size, turnover, gross value added, and employment and to assess their direct, indirect, and induced effects for value creation and regional economic development. A major problem is the lack of comparability of these studies. There are several reasons to this: lacking theoretical foundations, imprecise definitions, deviating classifications, country-specific conventions in the statistical aggregation of industries and occupations, and diverging methodologies and data sources for measuring economic impact. The classificatory models as well as the UNESCO and EU frameworks outlined above might help to achieve greater harmonization in the future (for a comparison of models, see Throsby, 2008b).

A comparison of national practices shows that nearly all European countries number the following domains among their classifications of the cultural industries (UNESCO-UIS, 2012: 51f.):

- Music
- Performing arts
- Visual arts
- Film and video
- Publishing (books, press, journals)
- Broadcasting (radio, television)
- Architecture
- Design.

A majority also includes cultural heritage, advertising, software, and computer games. Other domains like sports, tourism, botanical gardens/zoos, toys, wine/food, cultural education, and artistic training are rarely counted. Countries in the Asia-Pacific region seem to be more heterogenous in their

delineation of the cultural industries, while in most African countries cultural statistics are only beginning to emerge (UNESCO-UIS, 2012: 69ff.).

When mapping the cultural industries, industry and occupational classifications should be considered simultaneously. With their 'creative trident' model, Higgs and Cunningham (2008) argue that within the 'creative industries' there are not only 'creative specialists,' but also sizable numbers of 'business and support workers' such as secretaries. Conversely, members of creative occupations may very well work 'embedded' within other industries, such as designers in the automobile industry. Based on their calculations with the 2001 Australian census, each of the three groups accounts for roughly one-third of the total employment in the 'creative trident.' In **Figure 3**, we adapt this model to the 'cultural industries' and tie it to a center–periphery conception: The 'cultural core' of the workforce consists of people working in cultural occupations within the cultural industries; cultural specialists who are embedded in other industries constitute the 'cultural fringe'; and support personnel within the cultural industries may be termed the 'noncultural fringe.' Both employees and the self-employed are relevant here.

It is beyond the scope of this article to go into details with measurement issues. In fact, procedures depend heavily on the statistical nomenclatures and data sources being in use in the country under consideration. For example, in order to measure cultural employment of the three types in **Figure 3** among EU countries in a comparable way, ESSnet-Culture (2012: 139ff.) proposes to use the EU Labour Force Survey and to combine information on employer's main activity according to NACE ('Nomenclature générale des activités économiques dans les Communautés Européennes') and employee's occupation according to 'International Standard Classification of Occupations.' At world level, NACE corresponds to the 'International Standard Industrial Classification of all Economic Activities.'

Reports on the economic impact of culture rarely separate single components of the creation/production, dissemination, and consumption/reception process of cultural products. As interesting questions arise in each of these stages, we devote single sections to each of them in the remainder of the article.

Artists and Producers of Culture

Various 'status-of-the-artist' studies exist that try to describe and explain the social and economic situation of artists (Karttunen, 1998; for an overview, see Butler, 2000). To study artists and producers of culture, two approaches are feasible (Throsby, 2001). The first is the use of census data or social surveys containing very large sample sizes such as microcensuses that cover the population or labor force in general. Although artists are in principle adequately represented in these data, it can be difficult to identify them all. Census data is being criticized for assigning a single occupation to people based on the job they last performed or from which they derived the main portion of their income. Thus, multiple jobholding and temporary underemployment which are typical for artists get ignored. (Benhamou, 2011; Karttunen, 2001). Moreover, census data are limited to very basic information; important variables such as artists' working hours and income from artistic and nonartistic work are usually missing (Alper and Wassall, 2006). The alternative is to carry out special-purpose surveys on artists. They enable researchers to define who counts as an artist, to use a suitable sampling frame, and to collect information on artists' social background, education, working conditions, earnings, social security, time allocation, and career.

However, defining an artist is challenging. Frey and Pommerehne (1989) identify eight ways of determining artists:

- The amount of time spent on artistic work
- The amount of income derived from artistic activities
- Their reputation as an artist among the general public
- Recognition among other artists
- The quality of artistic work
- Membership in a professional artists' association
- Professional qualification in the arts
- Their subjective self-evaluation of being an artist.

The use of multiple criteria is recommended because only subpopulations are reached by each of them. A major example is the *Economic Study of Professional Artists in Australia* carried out five times since 1983 (Throsby and Zednik, 2010). Specific to these surveys is the definition of artists as professionally recognized in their respective art forms. To arrive at a list of potential artists, artists' unions and associations, published listings, and directories are consulted. From the consolidated list of names, a random sample is drawn for a screening interview. To be identified as 'professional artists,' respondents have to answer a number of screening questions measuring artistic success and involvement (like publishing, exhibitions, full-time training). Irrespective of their income, both full-time and part-time, employed and self-employed artists are incorporated.

Further sampling strategies and research designs do exist. For example, respondent-driven sampling has been suggested to identify 'hidden' artist populations, like jazz musicians (Heckathorn and Jeffri, 2001). Although panel studies of artists are rare, the career success of professionally trained artists can

	Employment within cultural industries	Employment within other industries
Employment in cultural occupations	1. Cultural core ('specialist')	2. Cultural fringe ('embedded')
Employment in other occupations	3. Noncultural fringe ('business and support')	4. Other

Figure 3 Model of the cultural workforce by industry and occupation. Model adapted from Higgs, P., Cunningham, S., 2008. Creative industries mapping. Where have we come from and where are we going? Creative Industries Journal 1, 17.

be traced on the basis of lists of art school alumni, as studies on visual artists in the Netherlands show (Rengers, 2002). In Finland, the register-based census enables researchers to track artists over several census waves by means of a personal code (Karttunen, 2001).

Dissemination of Culture

The dissemination of culture, in large part, takes place on an organizational basis. Hence, organizational and archival data are needed in order to study structures and processes in this part of the cultural process model. However, statistical systems are not well established in this field (for the United States, see Kaple, 2002; for Germany, see Rössel and Otte, 2010).

With regard to nonprofit organizations, arts service organizations – like museum, theater, or orchestra associations – are important bodies that collect data of their members, for example, on revenues, expenditures, and staff structures. These data are usually published in annual reports in aggregated form and rarely allow for differentiated analyses at the organizational level. Moreover, the coverage of these databases tends to be biased in favor of large organizations.

More often than not, rich data sources have to be developed and utilized by researchers in time-consuming collection and coding procedures. For example, archival data of orchestra repertoires can be used to study conformity and innovation in the musical canon (Dowd et al., 2002). Contents of newspapers and school exams can be analyzed to get information about the valuation of different cultural traditions and art forms in education and the public sphere (Bevers, 2005; Janssen et al., 2008). Business data are harder to obtain. Knowing about the artistic offerings and sales figures of publishing houses, labels, and galleries would be helpful to reconstruct the supply side of the market and to explain artistic success. Of course, data can be gathered by survey research. For instance, samples of museum directors and curators as well as art dealers have been surveyed with standardized questionnaires. Since 2001, an archive for data on the arts and cultural policy exists, the *Cultural Policy and the Arts National Data Archive* at Princeton University, offering study descriptions and data sets from the United States.

Consumption and Reception of Culture

Cultural Participation Studies

Research on cultural consumption, reception, and amateur production is conducted in 'cultural participation studies.' It relies on sample surveys of the population or of audiences of concrete cultural institutions. We focus on population surveys because of their potential for representative predications. They are either conducted by academic social research or, more often, commissioned by governmental institutions and official statistics. In the latter case, a main goal is to gain insight into public participation in the cultural infrastructure subsidized by the state. Therefore, cultural domains tend to be constricted to 'high' cultural institutions and cultural heritage.

Quite often, the target population of cultural participation surveys is the population aged 15 years and over living in private households of a country. The treatment of ethnic minorities varies: Sometimes people with limited abilities in the official language or with a foreign citizenship are excluded; sometimes ethnic minorities are oversampled. In Europe, typically multistage, random samples are drawn; data collection is mostly done through face-to-face interviews. The median sample size is about 4500 (ESSnet-Culture, 2012: 243). For the United States, an inventory of 29 studies is provided by Pettit (2000). Morrone (2006) provides insight into the measurement of cultural participation in Bhutan, Thailand, and Uganda.

Questionnaires usually consist of at least four modules:

1. Frequency of attending cultural events and institutions
2. Frequency of media-based cultural consumption at home
3. Frequency of performing artistic amateur activities
4. Sociodemographic characteristics of the respondents.

The set of core items is depicted in **Table 1** (for overviews, see ESSnet-Culture, 2012: 248ff.; Morrone, 2006; Pettit, 2000). Additionally, preferences are often surveyed with respect to

Table 1 Core elements of cultural participation surveys

Domain	*Cultural attendance*	*Home consumption*	*Amateur production*
Music	Live music concerts (by genres)	Listening to radio Listening to recorded music (and genre preferences)	Playing an instrument Singing
Performing arts	Theater Musical theater Opera Ballet/dance performances		Acting Dancing
Literature	Libraries	Reading books (and genre preferences) Reading newspapers/magazines (and arts-related interest)	Writing stories/poetry/novels
Visual arts	Museums (by types) Art galleries		Painting/drawing Producing craftworks Amateur photography
Film	Cinema	Watching TV, watching films on video/DVD (and genre preferences)	
Cultural heritage	Historical monuments Archaeological sites		

music, film, and literature genres as well as museum types. In extended surveys, modules for the socialization in the arts, possession of cultural goods, media use in a wider sense, the social context of attendance, cultural reception modes as well as subjective motives and barriers of attendance are added. In general, the breadth of cultural domains is considerably smaller than the UNESCO-UIS, (2009) FCS recommendations. For example, preferences for architectural or design styles are rarely investigated. It is striking that, despite of the common core of indicators, there is little agreement on the wording of questions, response categories, and other measurement issues (Schuster, 2007). One standard followed by most researchers is to use the reference period of the last 12 months for cultural attendance.

Table 2 lists a selection of large-scale cultural participation survey programs that are organized as repeated cross-sections. The U.S. *Survey of Public Participation in the Arts* is probably the most widely used data set. Although it has been conducted as a supplement to larger surveys and is lacking modules that go beyond cultural consumption, amateur production, and some basic cultural socialization, its sample size and regular repetition with similar questions make it a valuable tool. The Dutch *Amenities and Services Utilisation Survey* and the French *Pratiques Culturelles des Français* reach back in time even longer. A major series of yearly studies was started in England in 2005 with the *Taking Part* program on leisure, culture, and sport. Since 2012, part of it is organized as a panel study. In Sweden, national studies are carried out yearly since 1986. Although differing in focus, cultural attendance is investigated almost every time – resulting in a unique time series. *Cultural Participation in Flanders* is a very detailed and theory-driven study that comprises – beyond all the modules discussed above – cultural attitudes, social network information, and retrospective questions on participation in adolescence. The *Family Survey Dutch Population*, with its distinct life course perspective, is a good example of how to measure the accumulation of cultural knowledge and interests. In some countries, cultural participation modules are repeatedly part of general social surveys (Australia, Canada) or leisure surveys (Finland).

For international comparisons in Europe, the Eurobarometer is a good choice because it is a rare instance of a harmonized survey program. The 2001 pioneer study among 15 EU member states was replicated for the candidate countries in Central and Eastern Europe in 2003. A third study took place in 2007. The culture module was developed by the *Leadership Group on Cultural Statistics*. It contains information on cultural attendance, amateur activities, media use, possession of relevant equipment, and music preferences. Probably due to a self-selection bias of culturally interested respondents, the level of cultural participation is overestimated when compared to national reference surveys (Morrone, 2006). Even in this harmonized survey, comparisons are problematic because of different national meanings of terms like 'concert' and 'opera' (Madden, 2005). Methodological guidelines and a questionnaire for a harmonized survey on cultural participation are formulated by ESSnet-Culture (2012: 256ff.).

Time-Use and Household Expenditure Surveys

Some aspects of cultural consumption can be studied with time-use and household expenditure surveys. In time-use surveys, respondents record, for a few days, their hourly main and secondary activities in a detailed time diary. While such data are instructive for frequent, mostly home-based cultural activities, less-frequent practices cannot be studied adequately. The *Multinational Time Use Study* is an expost harmonization of national data, comprising 60 data sets from 25 countries in 2013. The *Harmonised European Time Use Surveys* program encloses data from 15 national studies and offers a guideline for harmonized data collection (Eurostat, 2009). An exhaustive list of cultural practices is provided by the ICATUS codes (UNESCO-UIS, 2009). In household expenditure surveys, household members' amount of spending on culture is usually included, but not broken down to cultural genres. The *Multinational Household Expenditure Study* and the European *Household Budget Survey* allow for international comparisons.

Conclusion

Although a common core of models and methods is detectable, the current state of cultural statistics is plagued by a multitude of proposals of how to define and classify culture, delineate the cultural industries, capture artists statistically, and measure cultural participation. The UNESCO and EU frameworks will certainly improve harmonized data collection in the future,

Table 2 Major replicative survey programs on cultural participation

Country	*Survey*	*Years*
Australia	Attendance of cultural venues and events (part of Multipurpose Household Survey (MPHS))	1991, 1995, 1999, 2005/06, 2010/11
Belgium	Cultural Participation in Flanders	2003/04, 2009
Canada	Supplement of the General Social Survey (GSS)	1992, 1998, 2005, 2010
England	Taking Part	Since 2005 yearly
Finland	Leisure Survey	1977, 1981, 1991, 2002
France	Pratiques Culturelles des Français	1973, 1981, 1988, 1997, 2008
The Netherlands	Amenities and Services Utilisation Survey (AVO)	Since 1979 every fourth year
	Family Survey Dutch Population	1992, 1998, 2000, 2003, 2009
Sweden	Kulturvanor i Sverige	Since 1986 yearly
The United States	Survey of Public Participation in the Arts (SPPA)	1982, 1985, 1992, 1997, 2002, 2008, 2012
European Union	Eurobarometer	2001/03, 2007

even though the inertia of national statistical systems should not be underestimated. Faced with diverging conceptual approaches, researchers should bear in mind that the utility and validity of concepts can ultimately be evaluated only if these concepts are linked to clearly stated theories, applied to practical research questions, and tested by their empirical performance.

Data Bases and Statistical Systems: Demography

Michaela Kreyenfeld, Hertie School of Governance, Berlin, Germany
Frans Willekens, Max Planck Institute for Demographic Research, Rostock, Germany

© 2015 Elsevier Ltd. All rights reserved.

Abstract

This article deals with the availability of large-scale data for demographic analysis. The main sources of data that demographers work with are censuses data, microcensus data, population registers, other administrative data, survey data, and big data. Data of this kind can be used to generate demographic rates and study demographic processes, such as family formation, marriage, divorce, residential mobility, and death. The advantages and pitfalls of different types of data are summarized.

Introduction: The Core of Demographic Research

Demography is the study of population dynamics and population structures. At the heart of this discipline lies the investigation of fertility, migration, and mortality processes. These processes determine the size and the composition of a population. Among the related issues that demographers investigate are partnership dynamics (including marriage, cohabitation, separation, divorce, and repartnering), residential mobility, aging, health, and retirement. A general principle that unifies demographic research is the firm conviction that demographic processes need to be located in time. Time includes two prime dimensions, namely, calendar time and age. An important tool used to visualize the age-calendar dimension is the Lexis diagram, which displays age on the horizontal axis and calendar time on the vertical axis (*see* Demographic Techniques: LEXIS Diagram). The diagonal lines in the Lexis diagram represent the aging of different birth cohorts. The evolution of demography as a discipline is strongly connected to the invention of the life-table technique, which originated in the works of John Graunt during the seventeenth century. Till today, life-table techniques are among the main methods demographers use in the study of age-related processes (*see* Life Table).

Demography is a discipline that relies heavily on the availability of large-scale data. During the seventeenth and eighteenth centuries, parish registers were the prime source of demographic analysis (Bengtsson and Dribe, 2006; Knodel, 1988). Genealogies have also been employed as sources in the reconstruction of the demographic behavior of historical populations (*see* Demographic Techniques: Family Reconstitution). With the formation of nation states in Europe during the nineteenth century, national governments developed an increasing interest in the size and structure of their populations. This interest later led to the establishment of national statistical offices. In Prussia, for example, the 'Königlich Preußische Statistische Bureau' was established in 1805. This office collected extremely rich population data, which are still used to study regional fertility dynamics (Lee et al., 1994). The 'modern' census was also created in this era.

A population census is an enumeration of all residents in a country or present in a country at the time of the census. The enumeration of all individuals necessarily implies that not more than a few characteristics can be recorded for each individual. More detailed information is usually collected from a selection of individuals that is representative for the entire population (microcensus). In addition to censuses and sample surveys, administrative processes are sources of information on the population. This data are a by-product of administrative processes. Civil registration is an administrative process by which a government records the vital events of its citizens and residents (e.g., births, deaths, marriages, divorces, migrations). Other administrative processes produce useful data too, e.g., tax collection, pension benefit payments, and issuing residence permits. A new source of data on individuals and their activities are tracking devices in sensors, mobile devices, credit cards, electronic identification cards, social media, Internet searches, and so on. Much of these data are generated in real time and are referred as *big data* because of their massive volume. Mayer-Schönberger and Cukier (2013) situate the emergence of big data in a historical perspective, with the census being the first systematic recording of information about members of a given population. The census could collect limited information only at periodic intervals. The modern tracking devices collect a variety of data in real time. In this article, brief descriptions of the main data sources are presented: census data, microcensus data, population registers, other administrative produced data, survey data, and big data. The processing of these data yields parameters of demographic processes (e.g., demographic rates) and indicators of population dynamics.

Census Data

A population census is a systematic recording of information on all members of a population usually residing in a country (*de jure*) or present at the time of enumeration (*de facto*). The United Nations (UN) recommends that censuses be conducted at least every 10 years, but countries vary greatly in the extent to which they comply with this guidance. The UN has provided a list of core aspects which the national statistical offices are expected to include in the census (United Nations, 2006): sex, age, marital status, employment status, level of education, country of birth, housing conditions, and household composition. Traditionally, censuses have been based on face-to-face surveys. However, in the most recent census, several countries

(such as the Nordic countries, Germany, The Netherlands, Slovenia, and Austria) have turned to register-based censuses in which several registers (e.g., employment, housing, and population registers) are combined. Such a census is sometimes referred to as a *virtual census*. Most other countries conduct traditional censuses in which the total population is interviewed face-to-face. Nonetheless, in some of these countries (e.g., Canada), the traditional census is a subject of political debate. The US Bureau of the Census has considered for decades how government records might help the traditional census-taking process. The use of these records raises concerns about personal privacy.

Censuses are of considerable importance for demographic research because they provide 'official' population counts for generating demographic rates by age and sex at the regional level. A key comparative project that makes use of the available census data is the Integrated Public Use Microdata Series (https://www.ipums.org/). Monitored by the Minnesota Population Center, the project makes harmonized census data available for a large number of countries around the world.

Microcensus Data

Most countries also conduct microcensuses on a regular basis. Microcensuses are surveys that are monitored by the national statistical offices and include a fraction of the total population. Microcensuses include data, which are richer than the data collected by censuses, and they are conducted in relatively short and regular intervals (often on a yearly basis). Among the forms of demographic information that come from microcensus data are, for example, the number of cohabiting unions in a population, the share of single-headed households, or the share of individuals in need of care. Because of their large sample sizes, microcensuses can provide more reliable indicators than social science surveys (see below). In addition, the nonresponse rates are very low in the microcensuses because participation is compulsory in some countries. However, microcensus or census data alone may not be sufficient for generating demographic rates because they often only contain cross-sectional information. However, methods have been developed that allow researchers to exploit microcensus and census data for demographic analysis. The 'own-child method' is a method that uses information on the number of children who live in a household at the time of a survey to reconstruct the fertility histories of women (Cho et al., 1986). This method is generally used for historical populations, but it may also be applied to contemporary societies when order-specific fertility data are not available from the vital statistics. In the 1980s, the UN published a manual of methods for deriving useful demographic indicators from census data. The manual has been updated recently (Moultrie et al., 2013) and is available online (http://demographicestimation.iussp.org/).

Population Register

Several countries, especially in Europe, maintain population registers or other types of registers that contain demographic data (such as birth, marriage or death registers). Individuals are legally required to report births, deaths, and migrations. When a marriage is performed in a civil ceremony involving a legal contract between spouses, marriages are registered and the data becomes part of the register. The dissolution of a marriage, or the end of a marriage contract, is registered too. In many countries, including most European countries, cohabitation has been on the rise since the 1970s. While some countries now provide the possibility to register a cohabiting union (such as France and the Netherlands), other countries (such as Germany) only provide this option for same-sex unions. Registered partnerships may, thus, also be captured in the civil registration system.

Registers that contain information of vital events are the prime form of data with which demographers work. The data generally contain counts of births, deaths, marriages, and residential moves. Births are commonly broken down by the age of the mother, the biological birth order of the child, the duration since the mother's last birth, and the mother's marital status. In most national statistics, birth statistics are only available by the mothers' characteristics. Marriage data are commonly broken down by aspects such as age, marriage order, and citizenship of the partner. Divorce data also fall into the category of demographic data, and are commonly available by age, marriage duration, and citizenship of the partner. Deaths are usually recorded by age, sex, marital status, and cause of death.

Migration data is often less widely available. Not all countries keep registers including data on changes of residence. If they do, internal and international migration statistics are derived from the registers. The quality of register-based migration data depends on reporting practices. If people do not report a change of residence and no system exists to track where people reside, migrations are undercounted. The undercounting is particularly frequent and extensive for emigrations, i.e., migrations to other countries. Some national statistical offices adjust international migration statistics regularly for undercounting. For instance, in the Netherlands, the official emigration statistics consist of emigrations reported and *administrative corrections*. Canada adjusts the number of immigrants. In most countries, though, undercounting goes unnoticed until the next population census. The 2011 census of Germany found 1.5 million people missing. Most of them are likely persons who failed to declare their emigration. The German statistical office had estimated that there were 7.3 million residents of Germany without German passports, but the census counted just 6.2 million. Residence is often not included in the migration registers. For instance, in the UK, the Office of National Statistics (ONS) uses three administrative data sources to produce internal migration statistics: the National Health Service Central Register, the Patient Register Data Service, and the Higher Education Statistics Agency data. To produce international migration data, ONS uses the census and the UK International Passenger Survey. Most official migration statistics tend to underestimate the volumes of immigration and particularly emigration, and to double-count circular and return migrants (United Nations Economic Commission for Europe and Statistical Office of the European Union, 2010). The difficulty of capturing illegal migrants in migration statistics is another source of serious error in the migration counts of some countries.

Differences in data sources, measurement schemes, and definitions of migration explain the lack of comparability of migration data across countries. Despite long-standing efforts to harmonize international migration statistics, the data are not fully comparable across countries (Lemaitre, 2005; United Nations, 1949). These discrepancies in international migration statistics become obvious when the migration flows between sending and receiving countries are directly compared (Raymer and Willekens, 2008).

Other Administrative Data

Administrative data (also called *process-produced data*) are data that are collected as a byproduct of administrative processes. Apart from birth, death, and marriage registers (see Section Population Register), tax, pension, employment, and registers of national health insurance providers may contain valuable demographic information. Administrative data are not subject to many of the problems associated with social science surveys, such as small sample sizes, high nonresponse rates, and the related underrepresentation of certain subpopulations (see below). However, countries vary greatly in terms of the availability of administrative data for demographic research; the Nordic countries of Europe are at the forefront of the development of such data (United Nations, 2007) (see also http://www.suda.su.se/simsam/). For other countries, data protection issues and difficulties in combining different types of administrative data create hurdles for this type of data analysis. In a time of shrinking response rates in social science surveys and the growing capacity of computers to manipulate large-scale data, the exploitation of administrative data is an obvious avenue for future demographic research. Several countries have already taken this route and have replaced their traditional censuses with register-based censuses in the most recent census round. The extent to which register-based demographic research will also be able to replace, enrich, or validate survey-based research is largely contingent on the willingness of the providers of administrative data to make their data available for scientific usage and the willingness of the national governments to promote and allow the linkage of different registers.

Social Science Surveys

Data from large-scale social surveys, which have become increasingly available since the 1980s, have revolutionized demographic research. Previously, demographers were primarily concerned with population data, which were mainly available at the aggregate level. But as a result of the wide availability of social science surveys, demographers have turned increasingly to the analysis of microlevel data. In addition, demographic techniques for microlevel data have advanced. In particular, the development of event history techniques has been paramount for demographic research. These techniques arose from classical life table techniques, but are also related to statistical methodology and modern regression analysis (Hoem, 1978; Mayer and Tuma, 1990). Sequence analysis and methods for displaying demographic behavior across the life course are also related to developments in event history techniques (Raymer and Willekens, 2008; Willekens, 1999).

To generate demographic rates with survey data, longitudinal data that locate the demographic events in time are needed. In this context, it is important to distinguish between retrospectively and prospectively collected data. *Retrospective data* are collected by asking people about their recollections of the timing and occurrence of past events. This information is usually gathered in a modularized way. In different sections of the questionnaire (*modules*), the different *domains* of a respondent's life course (like the fertility, residential, and partnership histories) are surveyed. This means that in these different parts of the questionnaire, the occurrence and timing of past events are recorded, often by relying on so-called *event history calendars*. In *prospective surveys*, life histories are reconstructed by reinterviewing each person at different points in his or her life course. This is done in a follow-up study (*panel survey*) in which the same respondent is reinterviewed on a regular basis (often in a yearly rhythm). By adding together the data gathered over time, it is possible to generate longitudinal information for the person. These data are, however, only partially comparable with the retrospectively collected life histories. A panel study only includes information on a person at different points in time in his or her life, and not for the person's entire life course. However, panel surveys usually also survey retrospective information that covers the last year or the time since the last interview. This type of information allows for the reconstruction of the person's complete life history, or at least the portion of the life history for the period during which the person participated in the panel study.

Retrospective Surveys

Compared to panel surveys, retrospective surveys are far less costly. Furthermore, while it takes several years to build up a panel survey, retrospective surveys can be used immediately for demographic analysis (Beckett et al., 2001). Moreover, for some processes, like cohabitation, a retrospective survey is the only tool for learning about past behavior, because no information exists from other data sources. Retrospective surveys have been important in helping us understand family behavior in contemporary societies. The World Fertility Survey (WFS), which was launched during the 1970s and early 1980s, was one of the largest social science surveys that collected fertility and family data for developing countries (Cleland and Verma, 1989). The WFS was followed by the Demographic and Health Surveys (DHS). DHS have been organized in a large number of developing countries and countries in transition (www.measuredhs.com). The Fertility and Family Surveys (FFS), which focused on developed countries, were conducted during the 1990s. The Generations and Gender Surveys (GGS), which were conducted around 2005, were similar to the FFS, although the GGS has also been conducted as a panel study in some European countries (http://www.ggp-i.org/). Some countries have a tradition of conducting cohort studies, in which the life courses of particular birth cohorts of women and men are surveyed. The British Cohort Study and the German Life History Survey are examples of cohort studies.

There are several advantages associated with the use of retrospective surveys, but also some significant pitfalls. The

largest problem that arises in conjunction with retrospective surveys is recall bias. Even salient events like marriage and childbirth have been shown to suffer from this distortion (Ní Bhrolcháin et al., 2011). For cohabitation, marriage, separation, and divorce, there is convincing evidence that recall bias, or the deliberate disclosure of information during the interview, poses a serious challenge to retrospective surveys (Mitchell, 2012). Another source of bias is related to sampling issues. In a survey, only the people who are residing in the country at the time of the survey are included. This population may have changed over time due to in- and out-migration. Thus, a retrospective survey cannot fully mirror the past behavior of the population resident in the country in the past. *Selection on survival* is another conundrum that is related to the fact that only the surviving population can be interviewed. Selection on survival may affect the analysis of family behavior, if, for example, fertility and family patterns correlate with mortality rates. The older the surveyed cohort, the stronger the bias. Obviously, demographic events like death cannot be studied with retrospective surveys unless proxy informants are used (e.g., information of a death of a person from other household members).

Prospective Surveys

Panel data may be used to overcome many of the shortcomings of retrospective data. A panel follows the same person over a certain period of time. Thus, mortality risks may also be investigated with a panel study, provided the information for the reasons why a person has dropped out of a panel is provided. One of the longest-running panel studies, which has also served as a model for many later surveys, is the Panel Study of Income Dynamics (PSID). Although these data were not surveyed for demographic purposes, they have been employed for various types of demographic analysis (Dowd et al., 2011). In the realm of family and fertility behavior, the National Longitudinal Survey of Youth, which was initiated in 1979, was one of the first large-scale panel projects that focused on family behavior. One recent American initiative is the Fragile Family Child Wellbeing Study. In Europe, the Netherlands Kinship Panel Survey and the German Family Panel are examples of more recent family panels (http://www.pairfam.de/en). They combine a cohort and a *multi-actor design*, meaning that in addition to the 'anchor respondent,' who is selected from specific birth cohorts, the respondent's parents and children are interviewed. One of the first and largest panel studies of the older population is the Health and Retirement Study, which was launched in 1992. For Europe, the Survey of Health, Ageing and Retirement in Europe is one of the landmark projects on the elderly (http://www.share-project.org/).

Panel surveys are indispensable for studying demographic behavior. In the realm of family research, they enable researchers to study how 'soft indicators' (like attitudes and values) affect subsequent fertility and partnership behavior. The relationship between employment and family choices has been studied using data from panel surveys, as there are very few registers that contain information about both employment and fertility careers. The growing availability of household and multiactor panels also provides researchers with the opportunity to study how the couple or household context influences fertility and family decision-making. For mortality research, panel surveys have been regularly employed to study how health-related behavior (like smoking habits) affects old-age disability or mortality. The inclusion of *biomarkers* (like grip strength, blood pressure, or even blood samples) in social science panel studies is an important new area that will help improve our understanding of the interplay of biological and social factors in family and health-related behaviors (McDade et al., 2007).

While panel surveys are very important for demographic research, there are a number of drawbacks to their use. One of the most significant problems associated with panel data is the issue of *attrition* (i.e., respondents dropping out of the study). Attrition is a general problem for any study that draws on a panel survey. But because of the strong correlation of attrition with residential mobility, it is a particularly severe issue for demographic analysis. Marriage, cohabitation, separation, divorce, or childbirth may lead to a residential move, and survey institutes are often unable to keep track of people as they move. A similar issue arises at higher ages, as respondents may be unavailable for an interview because they have moved into an eldercare facility, been hospitalized, or been unable to answer questions for other reasons (such as disability). The analysis of mortality risks using a survey is also contingent on the availability of information on the reasons why a respondent dropped out. Some panel studies (like the PSID and the US Health and Retirement Survey) are able to verify that a respondent dropped out due to death by linking his or her information to official death registers. In other countries, it is not possible to confirm deaths in this way. Another serious issue that affects social science surveys in general is the undercoverage of certain subpopulations. The underrepresentation of disabled individuals and people in eldercare facilities creates a problem for demographic analyses of transitions in the later life course. The undercoverage of young, mobile men, and the inability to properly capture nonresidential fathers, make investigations of family biographies, especially those involving male respondents, challenging (Rendall et al., 1999).

Big Data

Data generated in real time by various types of tracking devices are not used as often in demographic analysis. Zagheni and Weber (2012) studied international mobility using geolocation data generated when individuals log into the computer. IP addresses are mapped to geographical locations, and a person's duration of residence is identified by repeated logins. From that information, short- and long-term migration flows and the typical migration age profile can be produced. A user's IP address is recorded whenever the Internet is accessed. The IP address can be linked to other information on the user, such as cookies containing unique identifiers, purchases paid for by credit card, Internet banking, cameras in combination with image processing software, electronic medical records that include medical and treatment histories, administrative databases, or other databases containing personally identifiable information. From that information, a personalized profile that includes a variety of conditions and activities can be created. Profiling, i.e., the construction of

personalized profiles generated by record linkages and data analysis, is technically possible and offers opportunities for demographic analysis. Linked with Geographical Position Systems (GPS), detailed population profiles can be generated at street level. Whether that technology will be used on a large scale depends on the outcome of the political debate on the protection of personal data. The debate is not entirely new. In the 1980s, popular resentment in West Germany prevented the population census from being conducted. Some felt that the questions to be asked were quite personal and recalled the use of census data to target Jews and other minorities during the Nazi era. The Constitutional Court canceled plans for the 1983 census, and required a revision of the process. The modified census was eventually held in 1987.

Demographic Rates

Structure of Demographic Rates

Demographic indicators are generated by relating the number of events to the population at risk of experiencing an event. The numerator is defined by the number of events (births, deaths, and marriages) recorded in the civil registration system. The denominator is defined by the population count (or the risk population), which commonly comes from census data. Censuses are generally conducted at regular intervals. For the intercensal period, the population size is estimated through updates of the population count using information on the numbers of deaths and births and the volumes of in- and out-migration. As the time since the last census increases, population estimates are subject to increasing error, especially because migration data are often less reliable. In the past, inaccuracies in population estimates have led to inaccurate assessments of the mortality rates of migrants, as well as to erroneous conclusions regarding mortality at higher ages (Kibele et al., 2008).

Availability and Comparability of Demographic Rates

Demographic indicators for various countries are compiled by the United Nations, Eurostat, and the Organisation for Economic Co-operation and Development. These data contain a wide array of demographic measures (such as the share of nonmarital births, marriage rates, divorce rates, life expectancies, migration flows, etc.). However, data across countries are often not fully comparable. Migration data in particular often are not comparable (as was mentioned above). In addition, discrepancies also exist in the way in which births and deaths are documented. One difference concerns the documentation of the age at which an event occurred. Some countries collect data on vital events by the age reached during the year (ARDY method). Other countries record vital events by the age in completed years (ACY method). The Human Mortality Database (HMD) (2002–present) run by the University of California at Berkeley (United States) and the Max Planck Institute for Demographic Research (Rostock, Germany) (http://www.mortality.org/) seeks to harmonize mortality statistics. The database includes death counts, population counts, and life tables for more than 30 countries. The Max Planck Institute for Demographic Research (Rostock, Germany) and the Vienna Institute of Demography (Vienna, Austria) (http://www.humanfertility.org/) offer a comparable database for fertility data: the Human Fertility Database (HFD). The HFD contains birth counts, population data, and age-specific birth rates. A special effort has been made to collect order-specific fertility data, which allows for the generation of indicators such as the age at first childbearing or the share of childlessness by the birth cohorts of women.

Period and Cohort Measures

Demographic indicators may be distinguished by period and cohort measures. Period rates relate the number of events to the average population size in a given year. The *crude birth rate*, for example, relates the number of births to the midyear population in a certain year. The *general fertility rate* uses the number of women aged 15–50 as the denominator, based on the fact that only women are at risk of childbirth. The *total fertility rate* (TFR) is a measure that standardizes for the number of women of a given age. The TFR is conventionally interpreted as the number of children a woman bears over her lifetime if she experiences age-specific fertility rates observed in a given period. The decline in the TFR observed in most industrialized countries since the 1960s has been interpreted as an indication of shrinking family size. However, period measures, like the period TFR, are distorted by so-called 'tempo effects' (Bongaarts and Feeney, 1998). Tempo effects mean that annual birth (or death) rates may decline as vital events are postponed until (or occur) later in the life course (*see* Demographic Measurement: General Issues and Measures of Fertility). For fertility behavior, this is a nontrivial issue, because the age at childbearing is constantly subject to change. The increase in age at first childbearing has risen since the 1960s in most industrialized countries, a process which has suppressed period fertility rates. For mortality development, tempo distortions have resulted in an underestimation of longevity in contemporary societies (Oeppen and Vaupel, 2002). While demographers have developed so-called 'tempo adjustments' to correct for the distortions of demographic period measures, there is so far no consensus regarding which method should be used to correct for tempo effects (Sobotka and Lutz, 2011).

Demographic events, like births or deaths, are events that are situated in the life course of individuals. Period measures, which are by definition focused on a cross section, cannot fully account for this fact. Period measures are essentially 'synthetic' measures of demographic behavior. Cohort measures that give the number of children a cohort of women have had over their lives more accurately describe the fertility behavior of a population. The same applies to cohort mortality rates, which give the life expectancy of a certain birth cohort. The above-mentioned Human Fertility Database (HFD) and Human Mortality Database (HMD) contain cohort indicators that make it possible to display cohort fertility and mortality trends. The disadvantage of using cohort data is that the behavior of a cohort can only be fully assessed for 'completed' cohorts (Ni Bhrolchain, 1992). For fertility behavior, this means that the total number of children can be determined only after the members of a respective cohort have reached the end of their childbearing years. For mortality, this means that the last

member of a given cohort must have died before the cohort's life expectancy can be generated.

Conclusion

Vital statistics continue to be a prime source of data for identifying overall fertility, marriage, divorce, and mortality trends. But because of the small number of items that are usually included in this type of data, the extent to which these statistics can be used to explain the various facets of demographic behavior is limited. In particular, these statistics fall short in their ability to capture the recent changes in family patterns. Most national statistical offices only provide marriage and divorce data, and are unable to provide information about the occurrence and stability of cohabitation and other forms of nonmarital living arrangements, which have become prevalent in recent decades.

Vital statistics are also limited when it comes to generating 'real exposure rates' (or 'occurrence–exposure rates'). Demographic rates are generated by dividing the number of events by the '*exposure population*.' The exposure population is generated by summing up the 'person-years' or 'person-months' that a population has been at risk of experiencing an event. For *absorbing* demographic events like death, exposure may be generated from population counts. For *recurrent* demographic events – like births, marriages, and divorces – it is more cumbersome to generate real exposure rates based on the overall population counts. For second births, for example, only women who have experienced a first birth are at risk of having a second one, and thus only those women should be used to calculate second birth rates. For divorce behavior, only married individuals are at risk of experiencing divorce, and thus only these individuals enter the risk population. Failing to accurately pinpoint the risk population is a frequent distortion of demographic rates. However, most national statistics are unable to provide the types of information that would enable researchers to generate real exposure rates for fertility and nuptiality indicators. Survey data and administrative data must fill this gap. The question of to what extent 'big data' may be used for demographic analysis in the future remains open to discussion.

This article is reproduced from the previous edition, volume 14, pp. 9770–9777, © 2001, Elsevier Ltd., with revisions made by the Editor.

Abstract

The entry on 'Databases, Core: Economics' gives the readers an overview on the evolution and structure of micro- and macroeconomic databases. In this context, the article summarizes the history and recent development of several economic databases in the United States and beyond, including sample survey data, databases for households and for business establishments, as well as databases of official national accounts. In addition, it revises the distinction between cross-sectional and longitudinal data systems. Finally, the article concludes with a brief assessment of future developments.

Additions to scientific knowledge generally require interactions between theory and measurement. For example, the Hubbel Telescope provides astronomers with information about the universe, biologists have the Human Genome Project to provide them with a mapping of the genetic characteristics of the human species, and physicists have large-scale particle accelerators to allow experiments designed to identify types of matter that could not have been observed in the past because the instrumentation was not powerful enough. It is a common observation among scientists that the rate of scientific progress is a function of the degree to which new measurement techniques enable us to observe events that could not have been observed in the past.

What are the social science counterparts of the Hubbel Telescope, the Human Genome Project, and the particle accelerator? It turns out that, in the social sciences generally and in economics in particular, the evolution of the sample survey provides a close counterpart to the natural sciences' powerful measurement devices.

This article examines, firstly the evolution of sample survey data in economics, often called microdata and then discusses databases that represent households as well as those that stand for business establishments; before it revises the distinction between cross-sectional and longitudinal data systems. Secondly, the entry reflects on annual collections of the official national accounts data; additionally often referred to as macrodata, main databases that deal with economic processes and measurements of economic activity are considered; data systems and the principal features of a selection of the most important data systems both in the United States and in other countries are summarized. The article concludes with a brief assessment of future developments.

History of Economic Databases

The earliest use of quantitative empirical information in the development of economics as a science was probably in the living standards surveys conducted in the United Kingdom during the nineteenth and the early twentieth centuries. These early survey studies were descriptions of income, expenditures, and nutrition in cities or towns, and were designed to help understand poverty. Perhaps the best known studies are those by Charles Booth (1891–1897), and by Seebohm Rountree (1902), which examined York. Earlier work, more in the mode of intensive case studies than surveys, was carried out by Frederic LePlay (1855). Another set of very early studies was the establishment of firm surveys focused on measuring production. Systematic work along those lines was done in the United States during the early part of the twentieth century by Simon Kuznets and his colleagues at the National Bureau of Economic Research (Kuznets, 1941). The Kuznets studies were basically macro descriptions of change over time in the level of production in the U.S. economy, along with a variety of industry subaggregates. The information in these early studies was typically collected from sample surveys (or censuses) of business establishments, conducted by the U.S. Census Bureau.

A distinguishing feature of these early establishment measurements is that the basic microdata were not available to outside analysts. These studies were solely used to produce aggregate estimates for the economic system as a whole, and were not thought of as sources of information about micro-level economic behavior.

Over the twentieth century, there has been an explosion of economic measurements based on sample surveys. In the early part of the century the focus was mainly on business establishments and on the measurement of aggregate economic activity, as previously noted. Later in the twentieth century, starting with the Great Depression of the 1930s, microeconomic databases, particularly those relating to households, began to appear with increasing frequencies. In 1935 and 1936, for example, a massive study of household expenditures was undertaken by the U.S. Bureau of Labor Statistics (BLS), in an attempt to get a better understanding of the impact of the depression on living standards. The Current Population Survey (CPS), which provides the basic measure of unemployment in the United States, began in the early 1940s. The BLS conducted consumer expenditure surveys designed to produce weights for the Consumer Price Index as early as 1890, in 1935–36 as just noted, and in their current form in 1950, the early 1960s, and the early 1970s.

All of the sets of microdata just noted were designed and collected by governmental units. During the latter part of the twentieth century, these governmental efforts began to be supplemented with microdata collections funded by governments but designed and conducted in the private sector,

typically involving academic survey research units, such as the National Opinion Research Center (NORC) at the University of Chicago and the Survey Research Center (SRC) at the University of Michigan. These private sector microdata sets were almost entirely household data, and included the series of studies of consumer net worth titled the Survey of Consumer Finances (begun in the late 1940s), the National Longitudinal Surveys of labor market activity, the Panel Study of Income Dynamics, and the Retirement History Survey (all begun in the late 1960s). During the 1970, 1980, and 1990s there was a dramatic increase in both public and private household microdata collections (*see* Data Bases and Statistical Systems: Sociology). Finally, the past decades of the twentieth century saw the beginnings of publicly available business establishment microdata in the United States.

Establishment Economic Data Sets

Central Statistical Bureaus produce virtually all nationally representative establishment data sets. In the United States, which has a unique decentralized statistical system, establishment databases are typically collected by the Census Bureau and designed (and commissioned) either by U.S. Census Bureau or by the Bureau of Labor Statistics. As noted in the introductory remarks for this article, the major use of establishment databases tends to be macroeconomic rather than microeconomic, in that they are used to produce national estimates and industry distributions of production, wage costs, employment, fringe benefits, work hours, and so on.

The history of establishment databases sponsored by the BLS goes back to the 1800s, starting with occupational pay surveys. The current employment statistics series (CES) began at BLS in 1915, the unemployment insurance series (ES 202) was started in 1935, the Occupational Employment Statistics (OES) survey in 1971, the Employment Cost Index (ECI) series in 1976, the Employee Benefits Survey (EBS) in 1980, and the hours at work survey in 1981. All of these surveys are designed to produce aggregate statistics from which monthly, quarterly, or annual estimates of change can be calculated and used by policy makers and business forecasters. The microdata underlying these aggregates are typically unavailable to the research community, although there are occasional exceptions under tightly controlled circumstances.

Establishment databases that are the responsibility of the U.S. Census Bureau basically include a census of establishments in all industries conducted every 5 years (available starting in 1963), and an annual survey of manufacturing establishments (available starting in 1972). The census data for all industries are designed to provide, among other statistics, benchmark data for total production, price deflators, and product detail. The annual surveys of manufacturing provide data on shipments, wage costs, capital expenditures, materials consumption, and energy use.

These census data are, as with the BLS data described earlier, designed to produce aggregate industry statistics relevant to policy makers and forecasters. However, in recent years Census has tried to increase the use of the microdata in these surveys by creating data enclaves – Longitudinal Research Data Centers.

These enclaves exist not only at the U.S. Census Bureau, but have also been installed at a number of other locations (Boston, Pittsburgh, Los Angeles, and Berkeley). The intent is to encourage researchers throughout the country to use the microdata, with the expectation that such research will not only turn up interesting scientific findings but will also suggest improvements in the basic data.

There is somewhat greater use of establishment microdata in Western European countries than in the United States, largely because there appears to be a bit less concern with privacy (confidentiality) considerations in Europe. In some countries, establishment microdata can be combined with individual microdata, permitting, for example, analyses of the way in which worker wage trajectories vary with industry.

Structure of Microeconomic Databases

Microeconomic databases belong to one of four possible categories, depending on whether they sample households or firms, and whether they are cross-sectional or longitudinal. Whether surveys are cross-sectional or longitudinal depends on whether or not the same household or establishment is followed through time, or whether a new sample is drawn for each study so that the same household or establishment is never in consecutive studies except by chance. Studies can also be focused on households or individuals, often called demographic surveys, or they can examine business firms or establishments, often called economic surveys.

The great bulk of the microdatabases available to the scientific and policy communities for analysis consist of household or individual microdatabases, not establishment or firm databases. These household microdatabases tended to be cross-sectional earlier in the twentieth century, and increasingly longitudinal later in the century.

In part, this is due to the fact that the early databases were likely to be focused on a particular policy variable, where measurement of that variable was the principle focus of the study. Thus, for example, the CPS has a very large monthly sample of cases because its principle objective is to estimate the unemployment rate with great precision, not only for the country as a whole, but also for states and other geographic areas. The CPS has limited information with which to explain employment rates, but the very large sample provides a rich description of the level, change, and regional variation in unemployment rates. In contrast, microdata like the National Longitudinal Surveys or the Panel Study of Income Dynamics were designed as longitudinal microdatabases able to track and eventually model the dynamics of change over time.

These tendencies (for household microdata to be used more than firm or establishment data and for analysis to be increasingly longitudinal) are clearly visible in the published literature (Manser, 1998; Stafford, 1986). Over the period 1984–93, for example, there were over 550 articles in the major U.S. economic journals dealing with household microdata, compared with a little over 100 using firm or establishment microdata. Moreover, the great bulk of the latter were not based on nationally representative establishment data collected by the Census or by the BLS, but were typically local studies with the data collected by the researcher.

The very limited use of establishment data in the published literature compared with household data is probably due to three factors. First, until very recently it was difficult, if not impossible, for researchers to access establishment microdata in the United States, due to the (accurate) perception that privacy/confidentiality considerations were a much more serious problem for establishments than for households; after all, it is impossible to hide GM or AT&T in a microdata set. Second, the theory of household or individual behavior is much better developed than the theory of business behavior, probably due in part to the greater availability of rich household microdata. Third, microdata sets for establishments are likely to be produced in the public sector and to be designed to track change over time in policy-relevant aggregate variables. Thus they will be relatively strong on well-measured policy variables, and relatively weak on a rich set of explanatory variables – a combination that makes analysis of the data set less likely to show up in scientific journals.

The tendency for household studies to be increasingly longitudinal is probably due to two factors. First, it took the economics profession some time to discover the advantages of longitudinal over cross-sectional analysis, and to develop the appropriate statistical tools. Second, the earlier sets of public microdata were strongest at providing careful measurements of the policy-relevant variables that justified the survey, which requires only cross-sectional data; they were typically less strong on including the explanatory variables essential to successful longitudinal modeling.

The principal features of a number of microdatabases are summarized, including databases where the major focus is on measurement of a dependent variable (where the design is apt to be cross-sectional), and others where the focus is on providing a rich explanation of behavior (where the focus is likely to be on careful longitudinal measurement of a very large set of explanatory variables). The series that we cover in this discussion are mainly household data series available in the United States, but some information on microdatabases available from Western Europe, Asia, and the developing world is provided. The series covered includes the Surveys of Consumer Finances (SCF); the Survey of Consumer Attitudes (SCA); the National Longitudinal Surveys (NLS); the Panel Study of Income Dynamics (PSID); the Survey of Income and Program Participation (SIPP); the Consumer Expenditure Survey (CE); the Time Use survey (TU); the Current Population Survey (CPS); the Health and Retirement Study (HRS); the Luxembourg Income Study (LIS); the Living Standards Measurement Study (LSMS); and the British, German, and European versions of the Panel Study of Income Dynamics (the British Household Panel Survey, BHPS; the German Socio-Economic Panel, GSOEP; and the European Household Panel Survey, EHPS). A brief discussion of establishment databases is also included.

Survey of Consumer Finances

The SCF, sponsored by the Federal Reserve Board, was initiated just after World War II to provide some insight into the likely behavior of consumers who had accumulated large amounts of assets during the war, when many types of consumer goods and services were unavailable and thus a large fraction of income was saved. The early surveys contain detailed descriptions of asset ownership and amounts of assets held across a rich spectrum of financial and tangible assets – financial assets like savings accounts, checking accounts, CDs, stocks and bonds, in later years money market accounts, IRAs, and Keoghs, and so on, along with tangible assets like investment real estate, businesses and farms, and vehicles.

Growing dissatisfaction with certain features of the SCF data, in particular with the fact that total financial asset holdings as measured by the survey were much lower than total financial asset holdings as measured in the Federal Reserve Board Flow of Funds accounts, Federal Reserve Board support was substantially reduced after 1960. The series was continued with less financial detail and broader sponsorship during the 1960s, and basically came to an end in its original form in 1969. The series was revived in 1983 with a sampling feature aimed at remedying the substantial underestimate of asset holdings shown by all of the previous surveys. This design feature was the addition of a high-income/high-wealth sample of households selected from statistical records derived from tax files. SCFs of this sort were conducted first in 1983, and have been scheduled on an every-third-year basis since 1989. (The last available data is for 2010.)

In addition to the detailed asset data, the SCF contains a comprehensive income section, has occasionally obtained substantial data on the pension holdings of respondents from the companies providing those pension plans, has a relatively standard set of household demographics and typically contains other variables of analytic interest – savings behavior, subjective health status, inheritances received, intended bequests, and so on. Furthermore, over the 1983–89 and 2007–09 periods, the survey collected panel data to examine how the effects of changes in the value of specific types of assets and debts and other economic disturbances played out at the household level (Bricker et al., 2001: p. 1). (For more information about the SCF, see their website: http://www.federalreserve.gov/econresdata/scf/scfindex.htm.)

Survey of Consumer Attitudes

SCA began in the United States in the late 1940s, originally as a 'soft' introduction to the questions about detailed asset holdings and income sources obtained in the SCF. These attitude surveys moved to an intermittent quarterly basis in the early 1950s, to a regular quarterly basis in the early 1960s, and to a regular monthly basis in 1978.

The basic content of these surveys includes a set of measures designed to reflect consumer assessments of their current financial situation compared with the past, their expectations about future financial conditions, their expectations about business conditions during the next year and the next 5 years, and their assessments of whether the present is a good or bad time to buy durable goods. Three of these core consumer attitude questions are part of the U.S. statistical system of leading economic indicators. The SCA contains substantially more data than the indicator series, including information about expected price change, perceptions of the effectiveness of current economic policy, assessments of buying conditions for houses and cars, expectations about changes in unemployment rates.

Data on consumer attitudes based on U.S. experience are now routinely collected in a number of other countries, including Austria, Australia, Belgium, Canada, China, Czech Republic, Denmark, Finland, France, Germany, Great Britain, Greece, Hungary, Ireland, Italy, Japan, Luxembourg, Norway, Poland, Russia, Spain, South Africa, Sweden, Switzerland, and Taiwan. (Information about the SCA can be obtained from their website: http://www.sca.isr.umich.edu/.)

National Longitudinal Surveys

The Bureau of Labor Statistics at the U.S. Department of Labor sponsors the NLS. The surveys began in 1966 with studies of the age cohorts of men aged 45–59 and of women in the age cohorts of 30–44. Young men and women aged 14–24 were added in the late 1960s, and young men and women in the age cohorts of 14–22 (called NLSY) were added in 1979. The children of the 1979 cohort were added in 1986. Of the six cohorts, data collection on four are continuing, while data collection on the remaining two (the original older male cohort aged 45–59, and the cohort of young men aged 14–24 in 1966) have been terminated.

The NLS surveys combine respondent interviews with a series of separately fielded administrative data collections, especially for the NLSY and the children of the NLSY cohorts. The information collected directly from NLS sample members includes information about work, family, educational experience, home ownership status, pensions, delinquency, and basic demographic information. The administrative data collection includes school characteristics obtained for the young women and young men cohorts and for the NLSY group, as well as for the cohort of children of the NLSY. In addition, school transcripts including coursework and attendance records were collected for the NLSY respondents in the early 1980s, and similar information is being obtained for children of the NLSY. Finally, aptitude and achievement scores from standardized tests were transcribed from school records in the late 1960s for the young men and young women cohorts, in the early 1980s for NLSY respondents, and during 1995 for the children of the NLSY cohort. Summary pension plan descriptions are collected for the mature women respondent and/or their spouses who report pension plan coverage, and death certificate information was collected in the early 1990s for most of the deceased members of the older men cohort. (More information about the NLS can be obtained from their website: http://www.bls.gov/nls/.)

Panel Study of Income Dynamics

The PSID, started in 1968, was based on combining a sample from the Survey of Economic Opportunity, originally conducted by the Department of Health and Human Services in 1966 and 1967, with a probability sample of individuals 18 years of age and older. The sample was heavily overweighed from the beginning with relatively poor households, since the SEO sample was designed to study poverty and had a disproportionate number of poor households.

The PSID has unique design features that have contributed to its status as being (probably) the most widely used micro data set in the world. A critical design feature is the way in which the PSID continues to be cross-sectional representative of the full U.S. population while maintaining the longitudinal characteristic that enables analysts to trace the dynamic of change over time. Representativeness for the U.S. population (except for new immigrants) is maintained by following PSID family members who leave their original sample households and begin their own households. This feature ensures a continued representation of newly formed households in the sample, accurately reflecting how the population changes with the birth of newly formed households. Thus PSID members are born, live their lives, and die just as individuals in the population do, and PSID traces the original sample individuals through their entire lifespan accompanied by whichever family they happen to be attached to – the original family in which they were a child, a new family when they formed their own household, and so on.

The PSID content is directed mainly at labor force experience and economic status, with a standard set of demographics. The study is especially rich in terms of data on jobs, job transitions, and detailed sources of income from work.

In recent years, the PSID has added significant modules on new topics. Health status, health insurance coverage, and functional health began to be collected in the early 1990s; wealth measures were obtained at 5-year intervals starting in 1984; and detailed pension and savings data were first collected in 1989. The wealth measures have been particularly successful. In 1997/1999, a sample of 511 immigrant families was added to enhance representativeness. In addition to the original PSID sample the Child Development Supplement studied the dynamic process of early life experiences in three waves (1997, 2002/2003, and 2007/2008). Finally, the PSID has had a major influence on microdata developments in other countries. Counterparts to the PSID can be found in the British Household Panel Survey (BHPS), the German Socio-Economic Panel (G-SOEP), and the European Household Panel Survey (EHPS). (For more information about the PSID, see their website: http://psidonline.isr.umich.edu/default.aspx.)

Survey of Income and Program Participation

The SIPP was begun in the early 1980s, with the basic objective of providing much richer income information for households at the lower end of the income distribution who might be eligible for various types of government public assistance programs. Thus the survey contains considerable detail on work experience, participation in a variety of public welfare programs, and on sources of income, along with family composition, a few health measures, and a standard set of demographics.

The SIPP basically has a cross-sectional design, although a number of observations are obtained for each respondent household to obtain very detailed information about income flows and work experience. Thus the SIPP is conducted at 4-month intervals, with respondents providing information about the previous 4-month period. Respondents stay in the sample for approximately six quarters, although in recent years the duration of stay has been extended so that a more genuinely longitudinal feature is available. In addition to income, work

experience, program participation, and some health items, the SIPP also has a wealth module that is administered several times to each participating household. In 1996, the SIPP Executive Committee established the Continuous Instrument Improvement Group (CIIG) to improve the SIPP core instrument. For example, selected outgoing rotation groups from the SIPP were followed longitudinally to observe the impact of the 1990s welfare reform on income, labor force participation, and poverty. Results of such new alternative instrumentation (1999–2003) were then compared and analyzed, and the final instruments were delivered for implementation in the 2004 Panel. Recently, examples of SIPP content include questions on medical expenses, child care, retirement and pension plan coverage, marital history, adult and child well-being, and others. The 2014 SIPP Panel uses the SIPP Event History Calendar (EHC) that assists the respondent's ability to recall events accurately over the longer reference period. The aim here is to increase data quality and intertopic consistency for dates reported by respondents. (More information about the SIPP can be obtained from their website: https://www.census.gov/programs-surveys/sipp.html.)

Consumer Expenditure Survey

The Consumer Expenditure Survey (CE), conducted by the BLS, has the principal objective of providing weights for the calculation of the Consumer Price Index. These studies have a long history: the first survey was conducted in 1888–91, the next in 1901 to get a better measure of price inflation in food, the third in 1917–19 to provide weights for a cost-of-living index, the next two during the depression of the 1930s to look at poverty issues, and the sixth, seventh, and eighth in 1950, the early 1960s, and early 1970s, respectively. The current version began in the early 1980s, when the survey was modified to be a continuous study with new samples appearing approximately every other year.

The survey goes into enormous detail on household expenditures across a long list of major product classifications (e.g., clothing, food, recreation, travel, insurance, cars, household durables) and provides estimates of consumer expenditures over past time periods for these categories. In addition, respondents are asked to keep a detailed diary, where they report each item purchased over a 2-week period. The diary information and the expenditure data for the product classifications (e.g., clothing for the respondent, for the spouse, for any children) are then integrated to produce an estimate of total consumer spending. In addition to consumption data, the CES includes detailed information about income, and also has some asset data along with the standard demographics. (More information about the CE can be obtained from their website: http://www.bls.gov/cex/.)

Time Use Survey

Time Use studies have a relatively lengthy history, and actually go back into the very early part of the twentieth century when studies of local communities in the United States, and of cities in the then Union of Soviet Socialist Republics, were conducted. As a major survey effort designed to provide national data on both market and nonmarket activities, the Time Use studies effectively started in 1965, when a cross-national study of urban time use was organized by a set of researchers under the direction of the Hungarian sociologist Alexander Szalai (1972). The countries included Belgium, Bulgaria, Czechoslovakia, France, Federal Republic of Germany, German Democratic Republic, Hungary, Peru, Poland, United States, Union of Soviet Socialist Republics, and Yugoslavia. Subsequently, time use studies in the United States with roughly comparable methodologies were conducted during 1975–76, and during 1981–82. Other time use studies in the United States were conducted in the late 1980s and early 1990s, although some design differences in these later studies make comparability with the earlier 1965, 1975–76, and 1981–82 studies difficult. Most European (and some Asian) countries conduct time use studies periodically, typically every 5 or 10 years, with a common survey design.

The Multinational Time Use Study (MTUS) was created to allow analysis of cross-time and cross-national changes in daily activities. The origins of the MTUS go back to an initiative of Professor Jonathan Gershuny in the early 1980s. The early MTUS mainly European data sets collected in the early 1960s through mid 1980s into a common series of background variables and total time spent per day in 41 activities. The MTUS has currently grown to encompass over 60 data sets from 25 countries, including recent data from the harmonized European time use surveys (HETUS), the American Time Use Survey (ATUS), and other national level time use projects.

One feature of the time use studies that differentiates it from most other microdatabase efforts is the difference in design between the United States and other countries. All studies that focus explicitly on time use collect data for a (usually retrospective) 24-h period – a time diary, as contrasted to a series of questions about the frequency of a set of activities. For the most part, these studies have been used as parts of national accounting systems, in which the major focus is on attempting to estimate the volume of nonmarket work, travel, leisure activities, and so on, as a supplement to the National Income and Product Accounts. Thus the major focus of the MTUS is on the macroeconomic uses of time diary data.

In contrast, the ATUS time diary data in the United States have been designed for use in a microeconomic as well as a macroeconomic framework. For that purpose, data for a single day consist mainly of statistical noise, and multiple time diaries for different days of the week and seasons of the year need to be collected for each sample member. Thus the U.S. design specified that data were to be collected for two weekdays, one Saturday and one Sunday, weighted to produce an estimate of time use during a typical week. In contrast, time diary studies in Europe typically (but not always) collect data for a single day for each respondent; in some recent studies multiple time diaries are collected for each respondent, often getting information for both a weekday and a weekend day in the same survey. (See more on ATUS at: http://www.bls.gov/tus/data.htm.)

Data archives on time use studies are maintained at the Centre for Time Use Research. (For more information, see their website: http://www.timeuse.org/home.)

Current Population Survey

The CPS, probably the most widely reported survey in the United States, if not in the world, is basically designed to produce an estimate of the unemployment rate for the nation as a whole, as well as for geographic subdivisions like states or SMSAs. The CPS, started in the early 1940s, is designed to produce estimates of work status during the prior week, including time spent looking for jobs as well as time spent working, for a very large (about 72 000 cases) monthly sample. The survey is a very simple and very brief instrument that collects virtually nothing else besides the policy-relevant variables – unemployment and work status for the adult population in the United States – from which the unemployment rate for the United States as a whole, or for particular states or SMSAs, can be calculated. The CPS does have additional survey content, since there are a series of annual supplements that include such variables as a detailed assessment of family income, assessments of health status for family members. But the core CPS is a very brief interview focused almost entirely on employment and job search experience. (For more information about the CPS, see their website: https://www.census.gov/cps/.)

Health and Retirement Study

The HRS, sponsored by the National Institute on Aging and the Social Security Administration, was begun in 1992 with the recognition that the U.S. statistical system had virtually no current data focused on the work situation, health status, family responsibilities, and pension status of the very large cohort of Baby Boom individuals (those born between 1946 and 1964) who would be starting to retire in the early twenty-first century. The behavior of this cohort was thought to be critically important for assessing the societal stresses associated with the prospective dramatic change in the proportion of the working population to the older dependent population.

The study, which collects information every other year, was originally focused on the U.S. population between the ages of 51 and 61 (those in the birth cohorts of 1931–41). This design would provide information with which to model the labor force participation decisions of individuals who were (mainly) not yet retired but who would retire shortly. In subsequent years, the survey was modified from one designed to follow an original cohort through its retirement experience, to a continuing study of the U.S. population of age 50 and older. It was designed to follow the retirement experience of successive cohorts of individuals starting with those born between 1931 and 1941 and continuing with those born up through the Baby Boom years. Thus the current study includes the original cohort of those born between 1931 and 1941 (and their spouses if married), and includes other cohorts added in subsequent years (those born before 1923, those born between 1924 and 1930, and most recently those born between 1942 and 1947).

The content areas of the HRS were subject to much more than the usual amount of developmental work. Survey content is decided by a set of researchers organized into working groups and headed by a Steering or Oversight Committee. The criteria that were uniformly adopted were that variables that played well-defined roles in modeling retirement decisions (or other critical decisions, such as saving rates) were eligible for inclusion, but other variables were not. Thus, the working groups pulled together sets of variables measuring job characteristics and work history; family structure and intrafamily transfers; health status and health insurance; economic status, including both income and wealth; several batteries of cognitive tests; a set of probability questions relating to continued work activity; future health status; longevity, bequests, and so on; and detailed information about pensions. The magnitude, duration, and cost of this planning effort are unique and give every indication of having produced a very high quality data set; it is certainly possible that the HRS planning model represents the future of microeconomic database design activities. (For more information about HRS, see their website: http://hrsonline.isr.umich.edu/.)

Luxembourg Income Study

The LIS represents one of the few attempts to collect comparable data on economic status across a large sample of countries. The basic idea is to collect national data on all income sources from as wide a range of countries as feasible, process the data so as to make it as comparable as possible across countries, and then make these data available to the research and policy communities for analysis of differences in economic status and income distribution. The core of the LIS activities is to process the data collected by national statistical agencies, to have a staff of trained analysts interact with their counterparts in these national agencies, and to develop measurements of income and income components that are as comparable as possible across countries.

The most important goal for LIS is harmonization – reshaping and reclassifying the components of income or definitions of household structure into comparable categories. Such harmonization allows the researcher to address important social issues without having to invest countless hours in getting every variable that will be analyzed into a comparable format.

Since its beginning, the LIS project has grown into a cooperative research project with a membership that includes countries in Europe, North America, the Far East, and Australia. The LIS database now contains information for more than 40 countries for one or more years, covering over 90 data sets over the period 1968 to 2010. The countries currently in the LIS database include Australia, Austria, Belgium, Canada, Czech Republic, Denmark, Finland, France, Germany, Hungary, Ireland, Israel, Italy, Luxembourg, the Netherlands, Norway, Poland, Portugal, ROC Taiwan, Russia, Slovak Republic, Spain, Sweden, Switzerland, United Kingdom, and the United States. (For more information about LIS, see their website: http://www.lisdatacenter.org/.)

Living Standards Measurement Study

The World Bank established the LSMS in 1980 to explore ways of improving the type and quality of household data collected by government statistical offices in developing countries. The objectives of the LSMS were to develop new methods for monitoring progress in raising levels of living, to identify the consequences for households of current and proposed

government policies, and to improve communications between survey statisticians, analysts, and policy makers. To accomplish these objectives, LSMS activities have encompassed a range of tasks concerned with the design, implementation, and analysis of household surveys in developing countries. The main objective of LSMS surveys is to collect household data that can be used to assess household welfare, to understand household behavior, and to evaluate the effects of various policies on the living conditions of the population. Accordingly, LSMS surveys collect data on many dimensions of household well-being, including consumption, income, savings, employment, health, education, fertility, nutrition, housing, and migration. Three different kinds of questionnaires are normally used: the household questionnaire, which collects detailed information about household members; the community questionnaire, in which key community leaders and groups are asked about community infrastructure; and the price questionnaire, in which market vendors are asked about prices.

Because welfare is measured by consumption in most LSMS research on poverty, the measurement of consumption is strongly emphasized in the questionnaires. There are detailed questions on cash expenditures, on the value of food items grown at home or received as gifts, and on the ownership of housing and durable goods. A wide range of income information is also collected, including detailed questions about wages, bonuses, and various types of in-kind compensation.

LSMS-type surveys have been conducted in a long list of countries, including Peru, Ivory Coast, Ghana, Mauritania, Jamaica, Bolivia, Morocco, Pakistan, Venezuela, Russia, Guyana, Nicaragua, South Africa, Vietnam, Tanzania, Kyrgyzstan, Ecuador, Romania, and Bulgaria. For more information on the LSMS, see Grosh and Glewwe (1995). (See also the LSMS website at: http://go.worldbank.org/WKOXNZV3X0.)

Macro Databases

Standardized economic indicators at the macro level are central to mentor the economic activity of a country and to compare the outcomes internationally. While there is no known formula for describing economic activity, data can help policy-makers better understand their countries' economic situations and guide any work toward improvement. This part of the article covers the most common databases of economic activity, such as the National Accounts Main Aggregates Database, the OECD Main Economic Indicators (MEI) Database, and the World Economic Outlook (WEO) Database.

The National Accounts Main Aggregates Database

The National Accounts Main Aggregates Database presents a series of analytical national accounts tables for more than 200 countries and areas of the world from 1970 onward. It is the product of a global cooperation effort between the Economic Statistics Branch of the United Nations Statistics Division, international statistical agencies, and the national statistical services of these countries, first initiated by the Statistical Commission in 1947. The aim was to publish regularly the most recent available data on national accounts for as many countries and areas as possible. To enable a coherent, consistent, and integrated set of national accounts, internationally agreed recommendations were established, first stated in the so-called United Nations System of National Accounts 1993 (1993 SNA) and then in the updated version 2008 (2008 SNA). The SNA describes how to compile measures of economic activity accounts in the context of a set of internationally agreed concepts, definitions, classifications, and accounting rules. In addition, the SNA provides an overview of economic processes, recording, among others, how production is distributed among consumers, businesses, government, and foreign nations. More on the National Accounts Main Aggregates Database see online at: https://unstats.un.org/unsd/nationalaccount/madt.asp.

OECD System of Composite Leading Indicators

The OECD system of composite leading indicators (OECD CLIs) was developed in the 1970s to give early signals of turning points of economic activity. This information is of prime importance for economists, businesses, and policy-makers to enable timely analysis of the current and short-term economic situation. OECD CLIs are constructed to predict cycles in a reference series chosen as a proxy for economic activity.

The OECD Main Economic Indicators (MEI) database, which provides the main source for the selected indicators of the OECD CLIs, covers macroeconomic indicators for the following major subject areas: (1) GDP and its components and industrial production, (2) selected commodity output variables (crude steel, crude petroleum, etc.), (3) business and consumer tendency survey series, (4) selected manufacturing variables (deliveries, stocks, new orders, etc.), (5) Construction, (6) domestic trade, (7) labor market series, (8) consumer and producer prices, (9) money aggregates, (10) interest rates, (11) financial variables, (12) exchange rates, (13) international trade, and (14) balance of payments data. For more detailed information on the OECD CLIs see: http://unstats.un.org/unsd/EconStatKB/KnowledgebaseArticle10428.aspx.

OECD Statistics Portal (Including OECD Economic Outlook)

OECD also includes data and metadata for the current 34 OECD countries and selected nonmember economies in its OECD.Stat database and thus enables users to search for and extract data from across many databases under different themes. Among these databases, the OECD database on Economic Outlook allows the analysis of the major economic trends in the past from 1967 and over the coming 2–3 years. It covers the main economic issues and the policy measures required to foster growth in each member country. Forthcoming developments in major nonOECD economies are also evaluated in detail. It provides data on expenditures, foreign trade, output, labor markets, interest and exchange rates, balance of payments, and government debt. For the nonOECD regions, foreign trade and current account series are available. Sources for the historical data are publications of national statistical agencies and OECD statistical publications such as the Quarterly National Accounts, the Annual National Accounts, the Annual Labour Force Statistics, and the Main Economic Indicators. An overview of OECD.Stats' gathering and collation is online available at: http://stats.oecd.org/.

Eurostat's National Accounts

The Eurostat's section on 'National accounts' provides access to a selection of methodological and other background information regarding core national accounts aggregates such as Gross Domestic Product (GDP) and its main components. Data are compiled in accordance with the European System of Accounts 1995 (ESA 95), the EU manual for national accounts. Each Member States' data are first compiled by its own national accounts, through an institution appointed by its government, such as its National Statistical Office or its National Central Bank and then transmitted to Eurostat as agreed in the ESA95 transmission program (ESA95TP), which has legal status in the EU. In addition to the information on the Member States, limited information exists on EFTA countries, EU Candidate countries, the United States, and Japan. This information is obtained from the National statistical authorities. See more information on the Eurostat National Accounts online on their website: http://epp.eurostat.ec.europa.eu/portal/page/portal/national_accounts/data.

IMF's World Economic Outlook

The IMF publishes a range of time series data on IMF lending, exchange rates, and other economic and financial indicators. Manuals, guides, and other material on statistical practices at the IMF, in member countries, and of the statistical community at large are also available.

The WEO Databases and its Outlook Reports were established by the IMF to monitor economic development and policies in its member countries and in the global economic system. They were first created in 1970 and have been publishing since then during the biannual WEO exercise, which begins in January and June of each year and results in the WEO publication, which is released in May and October. The WEO database provides time series data for GDP growth, inflation, unemployment, payments balances, exports, imports, external debt, capital flows, and commodity prices. The World Economic Outlook Reports present IMF staff economists' analyses of global economic developments during the near and medium term. Chapters give an overview as well as more detailed analysis of the world economy; consider issues affecting industrial countries, developing countries, and economies in transition to market; and address topics of pressing current interest. The WEO exercise is coordinated by the World Economic Studies Division in the Research Department. The survey of prospects and policies is the product of a review of world economic developments, which draws primarily on the information IMF staff gathers through its consultations with member countries.

See also the WEO website at: http://www.imf.org/external/ns/cs.aspx?id=28.

World Bank Databases on Economic and Growth

The World Bank's data catalog is a listing of available World Bank data sets, including databases, preformatted tables, reports, and other resources aiming to provide all users with access to World Bank data. Regarding the topic 'economic and growth,' there are currently 26 reports found beginning from the World Development Indicators, which presents the most current and accurate global development data available, and includes national, regional, and global estimates, up to the Global Economic Monitor (GEM), which provides daily updates of global economic developments for exchange rates, equity markets, interest rates, stripped bond spreads, and emerging market bond indices. More information see the World Bank website at: http://datacatalog.worldbank.org/?Topics=Economy-and-Growth.

UNCTAD Statistics

The United Nations Conference on Trade and Development (UNCTAD) provides data on core themes via its online statistical database, UNCTADstat, in nine thematic areas: merchandise trade, trade in services, foreign direct investment, external financial resources, population and labor force, commodities, and maritime transport. Besides, the related annually World Investment Report contains many tables on global and regional, cross-border mergers, and acquisitions and transnational corporations. See more at their website at: http://unctadstat.unctad.org/ReportFolders/reportFolders.aspx?sCS_referer=&sCS_ChosenLang=en.

The Future of Economic Data

Developments at the turn of the century suggest that a continued expansion in the use of both longitudinal household data sets and internationally agreed standard economic data sets is likely to see, along with a vigorous growth in the use of establishment databases for micro- and macro-level analysis. These developments will be the result of three compelling forces: first, the increased ability of economists to understand economic behavior at micro-level and economic activity at macro-level based on the combination of richer theoretical insights and the greater availability of relevant data; second, the increased involvement of academic economists in the design of economic data sets; and third, referring to the micro databases, the development of more effective strategies for safeguarding privacy and confidentiality while still permitting researchers access to microdata files.

Data Bases and Statistical Systems: Economics (Macroeconomics)

Thomas P Hill, University of East Anglia, Norwich, UK; and National Accounts and Economic Statistics, OECD, Paris

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Macroeconomic data are built up from the aggregate values, for groups of economic units, of the market transactions associated with economic activities such as production or consumption. All the aggregates are defined and classified consistently with each other using the internationally agreed System of National Accounts. Changes in the values of economic aggregates over time can be factored into their quantity and price components using appropriate aggregate index numbers. Similarly differences between countries in the values of economic aggregates expressed in their own currencies can be split into their price and quantity components using purchasing power parities.

Introduction

Macroeconomic data cover groups of economic units at different levels of aggregation up to and including the economy as a whole, i.e., the entire set of economic units resident in a country. Most macroeconomic data measure the aggregate values of sets of transactions associated with economic activities such as production, consumption, or financing. However, macroeconomic data may also refer to the values, at a point of time, of stocks of physical or financial assets owned by groups of units. The distinction between a stock, which can only be measured at a point of time, and a flow, which can only be measured per period of time, is of course fundamental.

Macroeconomic data are meant to provide a comprehensive picture of the economic activities taking place within an economy. They are used to monitor short- and long-term changes in the level of economic activity. They provide the information needed for purposes of fiscal and monetary policy by governments and central banks and also the data needed for purposes of economic analysis and forecasting by governments, universities, research institutes, or other agencies. For these purposes, it is necessary to measure how much of the change in an economic aggregate is due to changes in the prices of the goods and services concerned and how much to changes in their quantities.

The first part of this article is concerned with the System of National Accounts (SNA) in which the values of macroeconomic aggregates are measured at current prices. The second part is concerned with the associated price and quantity indices. Price and quantity indices are important macroeconomic statistics in their own right. For example, consumer price indices (CPIs), which measure changes in the prices of consumption goods and services purchased by households, have traditionally been used for index linking; that is, adjusting wage rates or social security benefits for the effects of inflation. They are also used as proxies for general measures of inflation for purposes of monetary policy.

Macroeconomic data are inevitably subject to error. Some data are based on surveys of businesses or households conducted by statistical office specifically for the purpose, but others are estimates that draw upon more than one data source, including data collected by government agencies for administrative purposes.

As macroeconomic data need to be as up to date as possible for economic forecasting and policy making, there is considerable pressure from users to obtain the data as quickly as possible. There is inevitably a trade-off between timeliness and reliability when the underlying raw data only become available piecemeal and gradually over a long period of time. The earlier the estimates are made and released, the greater the risk that they may have to be substantially revised later when more data become available. Minor revisions seem be acceptable to users as the price to be paid for receiving data on a timely basis, but major revisions can undermine the credibility and usefulness of the data.

The Main Aggregates

Gross Domestic Product and Gross Value Added

Suppose the objective is to measure the contribution of an enterprise to the total output produced in a country. Measuring the output of a single enterprise on its own is straightforward. Following standard accounting practice, the output of an enterprise is measured by the value of its sales plus the value of the change in its inventories. However, not all of the outputs produced by resident enterprises may be destined for 'final' use (i.e., final consumption by households or government or adding to the stock of fixed assets) because some may be sold to other enterprises for them to use up as inputs into their production. Products that are used up in the production of other products are described as 'intermediate.' In order to measure the contribution of each enterprise to the economy's final output, it is necessary to deduct from the value of its output the value of all the intermediate products consumed in the production process whether the products have been produced by other resident enterprises or by foreign enterprises. The difference is described as 'gross value added' (GVA).

Value added may be measured 'gross' or 'net' of depreciation, i.e., the decline in the value of the stock of fixed assets – machinery, equipment, and structures – used in the production process. However, in practice, because of lack of information about stocks of assets it is often not possible to estimate depreciation, and hence net value added, satisfactorily. GVA is a simpler concept and much more robust measure and it is widely used for this reason.

Gross domestic product (GDP) is defined simply and precisely as the sum of the gross values added of all the enterprises resident in an economy. GDP is probably the most important single macroeconomic aggregate being used throughout the world as a key indicator of the level of economic activity. As GDP does not include the value of outputs sold for intermediate uses, it follows that GDP is equal to the sum of all the outputs sold for final uses, i.e., the sum of household and government consumption expenditures plus gross capital formation plus exports *minus* imports. This means that GDP can be estimated from final expenditure data as well as from production data – one estimate providing a check on the other. It is measured quarterly as well as annually, and usually in real terms as well as at current prices.

From GDP to National Income

The link between measures of production and income is established by the fact that GVA provides the source of the funds out of which all the incomes generated in the course of production can be paid. These incomes are now described as 'primary' incomes although traditionally they used to be called 'factor' incomes. They consist of wages and salaries, rents on land, interest on loan capital, and gross operating profits. Gross profits are defined as the residual amount of value added remaining to the owner(s) of an enterprise after all the other incomes have been paid. The sum of all the primary incomes generated by production including operating profits therefore equals GVA by definition. At the level of the economy, the sum of the incomes generated by production is described as *gross domestic income*, or *GDI*, which is equal to GDP by definition. Net national income is obtained by deducting total deprecation from GDI, although as already noted satisfactory estimates of depreciation are seldom available so that the aggregates have to remain gross.

From National Income to National Accounts

Until the first half of the twentieth century, interest in macroeconomic data was mainly confined to estimating the sizes of a few aggregates at a national level, especially national income. The development of comprehensive macroeconomic data systems dates back to the 1930s and 1940s. It was stimulated by a combination of factors including the great depression and the Second World War. The depression and the switch from peacetime to wartime production both led to more active economic policy making and government intervention, but such policies also require more information. The relevant macroeconomic theory and models were also being developed alongside the macrodata systems in several countries, for example, the UK, the Netherlands, and the USA.

The macroeconomic data systems were described as national accounts. The publication of official estimates of national income aggregates for the USA started in the 1930s, but it was not until the Second World War that proper accounts began to be published. The first set of official national accounts for the UK was compiled by James Meade and Richard Stone in 1941 in the UK Treasury under the guidance of Keynes. Toward the end of the war, very close links were established between economists in the UK and the USA which culminated in the elaboration of the international systems of accounts described later. The development of these systems was a collective achievement by a number of economists from Europe and North America, but the pride of place is generally given to Richard Stone who was awarded the 1984 Nobel Prize in economics for his work in this field. Stone took the leading role in elaborating the international systems published under the auspices of the United Nations and the Organization for European Economic Cooperation or OEEC (later the OECD).

Stone focused on transactions between economic units as the elementary bits of information from which macroeconomic data systems have to be constructed. The objective of economic accounting is to organize, classify, and aggregate the countless transactions taking place within an economy in a way that is informative and useful for purposes of economic analysis and policy making. The challenge that this presents is of a different order of magnitude from that of deciding how to define and measure a single aggregate such as national income.

In 1953, the United Nations published its "*System of National Accounts and Supporting Tables*," or *SNA*, intended for use by all countries in the world, although the Soviet Union and other Socialist countries chose to use their own Marxist version of the system, which they eventually abandoned in the early 1990s. Three major revision updates and extensions of the UN *SNA* have been undertaken and published since 1953 in 1968, 1993, and 2008. The revisions completed in 1993 and 2008 were organized and conducted jointly by all the interested major international economic agencies – *UN*, *IMF*, *World Bank*, the *OECD*, and the *European Union (EU)* – using a group of national experts from around the world. Each revision was approved by the Statistical Commission of the United Nations which consists of a cross section of Heads of National Statistical Offices throughout the world. Almost all National Statistical offices have adopted the SNA as the model or standard for their own accounts.

The International System of Macroeconomic Accounts

The first paragraph of the most recent 2008 version of the International System of National Accounts (SNA) (European Commission et al., 2009; paragraph 1.1) reads as follows:

> The System of National Accounts (SNA) is the internationally agreed standard set of recommendations on how to compile measures of economic activity in accordance with strict accounting conventions based on economic principles. The recommendations are expressed in terms of a set of concepts, definitions, classifications and accounting rules that comprise the internationally agreed standard for measuring such items as gross domestic product (GDP) the most frequently quoted indicator of economic performance. The accounting framework of the SNA allows economic data to be compiled and presented in a format that is designed for purposes of economic analysis, decision taking and policy making. The accounts themselves present in a condensed way a great mass of detailed information, organized according to economic principles and perceptions, about the working of an economy. They provide a comprehensive and detailed record of the complex activities taking place within an economy and of the interaction between the different economic agents and groups of agents, that take place on markets or elsewhere.

In the 1960s, the Statistical Office of the European Communities decided to develop its own variant of the SNA "intended to meet the needs of the economic and social policies of the European Communities." The EU variant is called the European System of Integrated Economic Accounts or ESA. The ESA is meant to be fully consistent with the SNA. It has been revised and updated in parallel with the 1993 and 2008 revisions of the SNA. The EU has also continued to play an active role in the revisions of the SNA in the same way as the other international agencies referred to earlier.

The Sequence of Accounts in the SNA

The accounts of the SNA follow a logical sequence which may be summarized as follows. The first account is a production account that records the values of the various inputs used up and outputs produced. The second records the primary incomes generated in the course of production and their distribution among different economic units. The third records the subsequent redistribution of the incomes as a result of taxation and social insurance schemes. The fourth records the use of disposable income for purposes of final consumption by households and government. The next two accounts record the values of the financial and nonfinancial assets acquired and disposed of during the accounting period. The system is closed by balance sheets that record the values of the stocks of assets and liabilities held at the beginning and end of the accounting period.

The difference between the total uses and total resources recorded on the two sides of an account is described as the 'balancing item.' GVA, profits, disposable income, and saving are all examples of balancing items that can only be measured within an accounting framework. The balancing items are typically the most interesting and important items within the accounts as they encapsulate a great deal of information about the activities in question. As already explained, *GDP* itself is a balancing item equal to the difference between the values of total output and total intermediate inputs in a simplified production account for the total economy.

Real Economic Aggregates and Inflation

In the national accounts at current prices, aggregate flows of goods and services are recorded at the actual prices at which the relevant transactions take place. However, many users want the changes in the values of the aggregates to be factored into their price and quantity components. In the case of GDP, for example, most users are more interested in changes in the quantity component, commonly referred to as the 'real' change in the aggregate or alternatively as the change in the 'real' aggregate, than in changes in the aggregate valued at current prices.

Index Numbers

Changes in prices and quantities at an aggregate level are measured by means of index numbers. The most well-known index is probably the CPI. CPIs pre-date the development of national accounts having been compiled and published for well over a century in some countries. The CPI is designed to measure the average rate of change in the prices of the consumption goods and services purchased by households.

Somewhat surprisingly, until recent years there were no detailed internationally agreed guidelines about the economically most appropriate methods to use to calculate CPIs, but at the end of the 1990s the same group of international statistical agencies that took on the responsibility for revising and updating the SNA decided to collaborate on the production of a new set of international guidelines for CPIs. This initiative lead to the publication in 2004 of a major new reference work entitled *Consumer Price Index Manual: Theory and Practice* (ILO et al., 2004). The manual contains an authoritative, comprehensive, and up-to-date survey of the underlying economic and statistical theory as well as practical advice about how to construct a CPI.

The most common type of price index is one that measures the change in the total value of a specified basket of goods and services between two time periods as a result of changes in their prices, holding the quantities constant. One advantage of this kind of index is that, conceptually, it is easy to see exactly what it measures. The difficult question is to decide which set, or 'basket,' of goods and services to choose. The index that uses the basket of the earlier of the two periods is called a Laspeyres index (Laspeyres, 1871), while the index that uses the basket of the later period is called a Paasche index (Paasche, 1874).

It is easily shown that the Laspeyres index as just defined is equal to a weighted arithmetic average of the ratios of the individual prices in the two periods, using the expenditures in the first period as the weights. (The Paasche is a weighted harmonic average of the same price ratios that uses the expenditures in the second period as weights.) If the price ratios and the corresponding ratios of the quantities in the two periods are negatively correlated, the Laspeyres index will be greater than the Paasche. There are good economic reasons to expect such a negative correlation, as rational utility maximizing consumers will react to changes in relative prices by switching their consumption away from goods and services whose prices have gone up most and replacing them by substitutes whose prices have gone up the least. This is known as the 'substitution effect.' The Paasche index will therefore tend to give less weight than the Laspeyres to goods and services that have experienced the largest price increases. The greater the variability in the prices ratios, the stronger the substitution effect becomes and the greater the 'index number spread' between the Laspeyres and the Paasche indices.

As both the periods compared are equally important, in principle there may be no reason to prefer the Laspeyres to the Paasche or vice versa. In these circumstances, the obvious compromise is to take some kind of average of the two. Several such averages can be envisaged, but the one that has attracted the greatest support is a simple geometric average of the Laspeyres and Paasche, proposed by Irving Fisher (1922). Fisher showed that the resulting index is a well-behaved index that has many desirable statistical properties: see Chapter 16 (by Erwin Diewert) of the *CPI Manual* (2004). It is known as Fisher's 'Ideal Index.'

The Economic Approach to Index Numbers

The economic approach to index numbers seeks to ground them in economic theory. The prime example of an economic

index is the cost of living index (COLI), an index that draws upon the economic theory of consumer behavior (Konüs, 1924). A COLI is defined as the ratio of the minimum expenditures in two periods that would enable consumers to enjoy the same standard of living or level of utility in both periods, other things being equal. Other factors besides price changes, such as environmental or political factors, can affect welfare. For example, a natural disaster, such as a tsunami or simply a very severe winter, will reduce welfare and cause an increase in the overall cost of living but it does not increase a COLI which is meant to measure only the effects of price changes on welfare or utility. A COLI is conditional on nonprice factors remaining constant.

A COLI is not just another index number formula but a different concept of index from one that measures the ratio of the costs of purchasing a fixed basket of goods and services in two periods. It is commonly assumed that CPIs automatically measure changes in the cost of living, but in fact cost of living indices as understood in economics are conceptually quite different from indices based on fixed baskets of good and services.

Consider a COLI based on the level of utility in the first period. It measures the amount by which consumers' expenditures have to be increased, or decreased, between the two periods in order to enable consumers to achieve the same level of utility in the second period as they enjoyed in the first; in other words, to leave consumers feeling as 'well off' in the second period as they were in the first. This is not at all the same as the amount by which expenditures have to be increased in order to enable consumers to continue purchasing the same set of quantities of goods and services in the second period that they did in the first (which is what the Laspeyres price index measures). When confronted with a new set of relative prices, a utility maximizing consumer would not choose to continue to purchase the same set of quantities as before because a higher level of utility could be achieved by adjusting the quantities purchased in response to changes in their relative prices – the substitution effect again. It follows that the Laspeyres index may be expected to be greater than a COLI based on the first period. If therefore the official objective of the CPI is to estimate a COLI, as it is in some countries, the Laspeyres must be viewed as having an upward bias. Conversely, a Paasche index may be expected to have a downward bias as an estimate of the COLI based on the level of utility in the second period.

The problem with a COLI is that the quantities that would be purchased in the second period if the prices were those of the first period are hypothetical. They cannot be observed or used to calculate the index. The COLI is not an operational index that can be calculated directly from the actual prices and quantities observed in the two periods. The best that can be done is to try to approximate to a COLI using indices that can be calculated, such as Laspeyres and Paasche indices.

As just explained, the Laspeyres index places an upper bound on a COLI based on the level of utility in the first period while the Paasche places a lower bound on a COLI based in the second period. However, there are some important special cases that provide useful insights into the interrelationships between the various indexes. In particular, if consumers' preferences are 'homothetic' (that is, the indifference curves at different levels of utility are all uniform expansions or contractions of each other), the COLI is invariant to the level of utility and hence to the choice of base period. In this case, the COLIs based on the first and second periods coincide, and the Laspeyres and Paasche indexes provide upper and lower bound to that COLI.

If consumer preferences can be represented by one particular type of homothetic function (a homogeneous quadratic utility function), the Fisher index is equal to the COLI; in other words, the Fisher index would provide an exact measure of the COLI. Even though it is generally agreed that consumer preferences are most unlikely to conform exactly with this particular functional form, it may be conjectured that the Fisher index is often likely to provide a fairly close approximation to the COLI. The mere fact that it is possible for the Fisher to coincide with the COLI has had a considerable influence on the attitudes of index number users and compilers.

Erwin Diewert (1976) took the analysis a step further by showing that a Fisher index is not the only type of index that may be expected to approximate a COLI. He showed that there is a whole family of indices, which he described as 'superlative' indices, that may reasonably be expected to approximate to a COLI, at least for small changes in the cost of living. A characteristic feature of a superlative index is that it treats both periods symmetrically. Another example of a superlative index is the 'Törnqvist' index, which has been widely used for the measurement of real output in studies of productivity growth.

The intuitive appeal of a symmetric index together with the theoretical underpinning provided by the concept of a superlative index has resulted in a situation in which some form of superlative index is generally regarded by economists as the best choice of index. Which particular superlative index is selected is a secondary consideration as superlative indexes may be expected to approximate each other, given that they all approximate the same underlying COLI. The Fisher seems to be the most popular and is recommended in the 1993 and 2008 SNAs for decomposing changes in the values of macroeconomic aggregates at current prices into their price and quantity components.

GDP and Welfare

In recent years, there has been an increasing tendency to criticize the concept of GDP because changes in real GDP, essentially a quantity index of the economy's output, may not reflect changes in people's welfare. It is worth recalling exactly how GDP is defined and what it actually measures.

At a microlevel, GVA is defined as the balancing item in a simplified production account for an enterprise. It measures the value of the goods and services produced by an enterprise *less* the value of the goods and services produced by other enterprises that it consumes as intermediate inputs in the process: it is the value created by the production carried out within the enterprise. At a macrolevel, GDP is defined simply as the sum of the GVAs of all the enterprises resident in the economy. GDP therefore measures the total value of the outputs produced that are available for final use, i.e., final household and government consumption, gross investment, or

exports. Only part of GDP is destined for consumption by households so that movements in real consumption generally do not coincide with those in real GDP.

As its name suggests, GDP is a measure of output and hence of the level of production taking place in the economy. This information is extremely important in its own right for economic analysts and policy making. For example, levels of employment and unemployment depend directly on the level of real GDP.

As GDP measures enterprise production, there is no justification for using it to measure the welfare of households. The introductory chapters to both the 1993 and the 2008 SNAs make it quite explicit that GDP is designed to be a measure of production and not welfare.

It is important to remember that the purpose of compiling national accounts is not to estimate a single statistic, such as GDP, but to obtain a comprehensive database of interrelated and interdependent macroeconomic statistics that include data on income and consumption as well as production. The SNA is meant to be a multipurpose system that can meet a variety of different user needs. The particular set of statistics chosen by a user depends on the user's purpose.

In the present context, welfare is understood to refer to the standard of living, or more generally the level of well-being, experienced by persons or households. This depends mainly on the volume of goods and services that persons consume to satisfy their own personal needs and wants. If the objective is to track changes in household welfare, the relevant statistics are those for household real consumption.

Changes in real household consumption or preferably changes in per capita real household consumption may be expected to provide a good indicator of changes in household welfare. Given that consumption data are actually available within the national accounts database, choosing real GDP instead, i.e., data on enterprise production, as an indicator of welfare would be illogical.

As GDP may not perform well as an indicator of welfare, many users have reacted by arguing that this shows that the concept of GDP is faulty, whereas the fault actually lies with the users for making an inappropriate choice of welfare indicator.

In recent years, there has been a considerable upsurge in interest in the measurement of economic welfare which has stimulated a great deal of research. It has also lead to the creation of a small number of special high-level expert groups to advise on ways to develop new improved measures of welfare, notably the "*Commission on the Measurement of Economic Performance and Social Progress*" set up in 2008 by Nicholas Sarkozy when he was President of France. The Commission which included two prominent Nobel Prize winners, J.E. Stiglitz and A. Sen, issued its report in 2009.

There appears to be some consensus that series of real per capita household consumption provide a good starting point for measuring household welfare but that such measures are by no means sufficient on their own because they do not take account of all relevant factors, especially the distribution of income and wealth among households. It has always been recognized that the distribution of income and wealth has a major impact on social welfare, but macroeconomic databases, almost by definition, do not include the kind of detailed microdata needed. The development of new micro-databases to complement the macro-databases of the national accounts is likely to remain a high priority for further research.

Internationally Comparable Macroeconomic Data

Purchasing Power Parities and International Comparisons of Real Expenditures and Real GDP

The most important innovation and development in the field of macroeconomic statistics in the last few decades has been the estimation of international purchasing power parities (PPPs), which enable international comparisons to be made of real GDP and other major macroeconomic aggregates.

The first international comparisons were made between a few of the member countries of the OEEC by Milton Gilbert and Irving Kravis in the early 1950s. The Statistical Office of the European Communities started to make comparisons among its own member countries in the late 1960s and early 1970s and has continued to do so on a regular basis ever since. The United Nations embarked on a set of world wide comparisons for 10 countries in 1970 and then repeated them roughly every 5 years thereafter gradually extending the comparisons to more and more countries. The UN program, known as the *International Comparisons Project* or *ICP*, was carried out under the direction of Irving Kravis, Alan Heston, and Robert Summers of the University of Pennsylvania (Kravis et al., 1975). Responsibility for the ICP was taken over by the World Bank in the late 1990s with the support of the other international statistical agencies. The latest sets of world wide comparisons covered 141 countries in 2005 and 200 countries in 2011 (World Bank, 2012). The ICP seems to be the largest and most ambitious program in economic statistics ever carried out in the world. It requires substantial contributions from all the 200 participating statistical offices that collect and transmit all the requisite basic price and expenditure data to the ICP team at the World Bank. It inevitably takes some years to collect and process all the data and finalize the results.

Bilateral comparisons between pairs of countries have much in common with comparisons between two time periods for a single country with the additional complication that prices in different countries are usually denominated in different units of currency. The ratio of the prices in two different countries for a single unit of quantity of some specified product is described as the PPP for that product. It measures the rate at which a unit of currency for one country has to be converted into a unit of currency of the other country in order to ensure that it will purchase the same quantity of the product in both countries. PPPs vary from product to product when the patterns of relative prices in two countries are not the same so that most product PPPs must differ from the market exchange rate as determined on currency markets.

Some kind of average of the individual PPPs is needed in order to estimate the purchasing power for an economic aggregate. In a bilateral comparison, if one country is selected to act as the base country, a Laspeyres type aggregate PPP can be calculated as a weighted average of the individual product PPPs that uses the expenditure shares in the base country as weights. It shows the rate at which the currencies of the two countries would have to be exchanged in order to ensure that the total amount of currency needed in order to buy the basket of

products in the base country would, after being converted into the currency of the second country, be just sufficient to purchase the same basket of products in the second country. By now, there is overwhelming evidence from the international price comparisons that have already been carried out to show that aggregate PPPs tend to differ significantly and systematically from market exchange rates. Market exchange rates cannot be used as proxies for PPPs, whether at the level of an individual product or at higher levels of aggregation.

In international comparison projects, each country is asked to supply both price and expenditure data for the same list of products, making it perfectly feasible to calculate symmetric indices. The results show that Laspeyres PPPs tend systematically to exceed the corresponding Paasche PPPs, at least for consumption aggregates. The substitution effect is at work even more strongly in international comparisons than in intertemporal comparisons as consumers tend to buy relatively more of products in countries in which they are relatively cheap. The index number spread between the Laspeyres and Paasche PPPs can be quite large because patterns of relative prices can vary substantially between countries, not only as a result of differences in income levels but also differences in preferences due to differences in culture, religion, or climate. In these circumstances, symmetric indices, such as Fisher, become particularly attractive, especially if it is felt that equal weight should be given to each country as a matter of principle.

In the late 1970s, the Statistical Office of the European Communities decided to adopt a bilateral approach to multilateral comparisons in which the first step is to estimate the 'best' bilateral indices for every pair of countries in the group; Fisher PPPs were selected for the purpose. The problem that remains is that Fisher PPPs are not transitive, transitivity (or circularity) being generally regarded as an essential property for a set of multilateral PPPs. However, transitivity can easily be imposed on a set of bilateral PPPs by applying the so-called 'EKS' formula or method (*CPI Manual*, 2004: p. 500). The EKS method calculates the set of transitive PPPs that collectively deviate the least from the original bilateral PPPs. Eurostat has continued to use EKS-Fisher PPPs up to the present time.

There has always been controversy about the best method of calculating a set of transitive multilateral PPPs and their associated quantity indices. From the outset, the UN ICP has preferred to use the 'Geary-Khamis' (GK) method (*CPI Manual*, 2004: pp. 500, 501) in which the quantity comparisons are made by revaluing the quantities in different countries at a common set of average international prices. The international prices are weighted averages of the national average prices after they have been converted into a common currency using the aggregate PPPs. The PPPs and the international prices are derived simultaneously by solving a set of simultaneous equations (Kravis et al., 1975: pp. 67–70; *CPI Manual*, 2004: pp. 500, 501).

In the GK method, the group of countries as a whole, rather than an individual country, acts as the base for making the comparisons. The method can be interpreted as being equivalent to one in which a Laspeyres type quantity index is calculated for each country based on the group as a whole, the quantity indices between the individual countries being derived indirectly from their respective quantity indices based on the group (Hill, 1997). Deriving the indices indirectly is a valid procedure because Laspeyres type quantity indices that use a common set of prices are transitive. One advantage of the GK method is that it can be seen how the composition of the group of countries as a whole influences the price and quantity comparisons between individual member countries of the group. Another advantage is that as the aggregates in different countries are all valued at a common set of international prices, they can be summed directly across all the countries in the group to obtain the values of the same aggregates for the group of countries as a whole. National accounts aggregates, including GDP, can be assembled for the group as a whole.

The pros and cons of the two main approaches to international comparisons – the EKS-Fisher and the GK methods – continue to be debated in the literature. An EKS-Fisher PPP is a minimally adjusted superlative index which may be expected to provide an unbiased estimate of the PPP. On the other hand, the GK method does not treat each country equally because the national average prices of economically large countries carry more weight in the average international prices than the national prices of smaller and less developed countries. The pattern of average international prices is inevitably dominated by prices in the larger and richer countries, if it is to reflect the economic realities of the global economy. However, it can be argued that a bias is introduced into world wide comparisons because of the upward biases inherent in Laspeyres type indices. This bias is not uniform from country to country but tends to increase the more the pattern of prices in a country diverges from the pattern of average international prices. The upward bias is likely to be greatest for poor developing countries whose relative prices are likely to diverge the most from the relative international prices. If so, the GK method is likely to introduce a bias into comparisons between developed and developing countries which causes the gaps in living standards and per capita real GDPs between rich and poor countries to be underestimated. The systematic overestimation of the real GDPs of small developing countries relatively to large developed countries has been labeled the 'Gerschenkron effect.' It is viewed as a major problem by many economists as inequalities in per capita income and product at a world level are matters of serious economic and political concern.

The controversy over which of the two methods is better for most purposes is still not finally settled. The differences between the results obtained using the EKS-Fisher and GK methods illustrate the sensitivity of macroeconomic data to the methodology used to compile them. Notwithstanding concerns about the Gerschenkron effect, the ICP is a monumental achievement in the field of economic statistics that has created a major macroeconomic database that is unprecedented in its scope and the sophistication of its methodology.

Abstract

The article on economic statistics comprises two major subjects. It touches upon the structure of economic statistics and describes how they are related to the system of national accounts. It also examines the major developments brought about in these statistics through the use of government administrative records, principally those related to taxation. The major development in economic statistics, 50 years ago, consisted in replacing cumbersome economic censuses by sample surveys that could be administered more frequently and at less cost. Developments today, however, mostly brought in by massive computer applications may make it possible to return to the census approach by using for statistical purposes what is collected anyway, as the government discharges its legal and operational responsibilities.

'Economic statistics' is used in its narrow definition as statistics produced by official statistical agencies and derived from direct surveys or from government administrative records. Economic statistics concern households, businesses, government and nonprofit institutions, their reactions to changes in the economic environment, and interactions with each other. They are shown as values, prices, and quantities and deal with production, distribution, the use of factors of production, and the ways and circumstances at which they are bought and sold. Economic statistics are essential to compile the national accounts (qv). They are presented typically in terms of the activity of the agents to which they relate or in terms of the product produced, sold, or consumed. These presentations are embodied in international classifications used by most countries and developed at the request of the United Nations and other international and supranational agencies. Economic statistics are derived from either economic censuses or administrative registers. The latter are increasingly popular because their use for statistical purposes does not represent an added cost and the powers of the agencies that compile them tend to ensure better and more thorough coverage. Sample surveys of business have also become increasingly popular particularly when designed to measure the changes in effective demand as a basis for macro stabilization policies. Today's more advanced statistical offices show data relating to the activity of business, their production and balance sheet, the sales and purchases of goods and services to and from countries abroad, and the changes in the price level as well as the participation of households in the national labor force. The consumer price index (definition) and the rate of unemployment have become the two key indicators watched by government policy makers.

Nowadays it is customary to include under economic statistics, information on science and technology, innovation, and estimates of the value and quantity of stocks of natural assets and measurements of the state of the physical environment.

Definitions: The Different Kinds of Statistics

Economic Statistics and Official Statistics

In its strict sense the term economic statistics has a narrower scope, as a distinction is drawn between economic statistics and economic accounts (as in the national or international accounts). For purposes of the present article the term 'economic statistics' excludes the national accounts but includes the statistics that are simultaneously used for economic and social purposes. Some statistics occupy a gray area – between social and economic statistics. They comprise measurements that play a role in describing social conditions and are used intensively in the making of social policies but at the same time relate intimately to the economic fabric of society. Examples are the statistics on income distribution commonly used for the measurement of poverty, the occupational makeup of the labor force, the expenditure patterns of households, and the structure of their income. Most of the references in this article apply to official statistics, i.e., those statistics that are either produced by government statistical agencies or by other bodies but are legitimized by being used by government. The usage adopted corresponds to the way in which government statistical offices are commonly organized.

Economic Statistics and Business Statistics

The kernel of economic statistics is formed by statistics related to business and derived from questionnaires addressed to business, business employees, or from official records, which businesses create in their dealings with government. Such statistics include descriptions of the business activity (what does the business produce, how does it produce it, for how much does it sell, what is the surplus generated by the sale once materials and labor are paid for, etc.) as well as of the nature of the factors engaged in production (structures and equipment used in production by type; labor employed by type of skill and occupation), and in addition statistics on the type of customers who purchase goods and services from businesses.

Data-Gathering Methods

Directly Measured Statistics and Derived Statistics

The term economic statistics is usually applied to statistics based on direct measurement, i.e., either from surveys addressed to economic agents or official administrative procedures that yield numerical data capable of being transformed

 http://dx.doi.org/10.1016/B978-0-08-097086-8.41070-6

into statistics. For example, the statistic on the national output of cement is usually established by directly asking all (or a sample of) cement producers, how much cement they produced over a defined period. The statistic on how many jobs were filled during a given period may be taken from the social security forms that employers are requested to send to the social security administration from time to time.

This is different from the way in which the economic accounts of the nation, the so-called 'derived statistics,' are collected. These are formed by combining all the existing economic (or basic) statistics through an interrelated system of accounting identities and from those inferring identity values that may not be available directly. They are also a means of assessing the strengths and weaknesses of economic statistics by noting how close they come into balance when the system of identities is applied to them. In other words, economic statistics are the raw material on the basis of which the economic or national accounts are compiled. The compilation of the national accounts in addition to summarizing and systematizing economic statistics plays the important role of showing up gaps in the range of economic statistics required to describe the functioning of the economic system (Table 1).

How Economic Statistics Are Measured

In spite of the increasing popularity of using administrative records as sources to generate economic statistics, economic statistics are compiled mostly from surveys addressed to business. Generally speaking, the surveys consist of the following: a list of respondents, a formal questionnaire – which can be used as a basis for a personal interview (or an interview by telephone or the Internet), a procedure followed when dealing with exceptional cases (not finding the right person to whom the questions should be addressed, finding that the business is not in the expected activity, or that the answers are incomprehensible or contradictory) – and a set of steps designed to aggregate individual answers so as to produce statistical totals, averages, or measures of distribution.

Problems of Defining What Is a Business

Part of the process of conducting a business survey consists in locating the addressees – either all the addressees in the survey universe if the survey is of a census type or some of the addressees if it is a sample survey. In either case two issues must be settled beforehand: (1) that all the addressees conduct the activity they are supposed to and (2) that there is no one else who conducts the targeted activity and has been left out. A related question has to do with what is a business. The term 'business' can be defined as the entity that is liable under the law to pay taxes; that has a management capable of deciding its scale of operations and how those operations should be financed; and that inter alia conducts the activity that is germane to the survey. An alternative definition is one that seeks that part of the business (and only that part) that engages in the target activity directly and excludes all other parts of the business. In either case it is important that the respondents to the survey understand the scope of the questions and are capable of answering them out of records available to the business's management.

Business Records

Businesses tend to keep all the records they require to ensure informed management in addition to what they have to keep in order to comply with tax authorities and any other regulatory

Table 1 Types of economic statistics and sources (in italics) from which they are derived

Economic agent	*Production*	*Distribution*	*Resources employed*	*Prices*
Households	Household income/*surveys of household income*	Wages and salaries/*surveys of household income, labor force surveys*	Current population estimates, participation in labor force, employment/*labor force surveys*	Consumer prices and consumer price index/ *surveys of prices*
Business	Value and amount of production; production by type of activity and by goods and services produced, orders and deliveries/*censuses and surveys of business activity*	Value and amount of sales; stocks of finished goods, materials and goods in process; sales by activity of seller and by-product sold; sales by type of customer (exports and imports)/*censuses and surveys of business activity; customs records*	Numbers employed by occupation; remuneration of labor employed; capital assets used; depreciation; profits; loans and equity borrowing/*censuses and specialized business surveys; company balance sheets*	Producer prices; unit values in manufacturing; producer price index/ *surveys of industrial prices, surveys of service activities, current agricultural surveys, customs records*
Government (central and local, public sector corporations, etc.)	Government expenditures and revenues by function and by source/ *public sector accounts*	Public sector sales of goods and services/*public sector accounts*	Public sector employment; public sector wages and salaries/*public sector reports; budget and supporting accounts*	Prices subject to regulation/ *special price surveys*
Other (nonprofit organizations, labor unions, employer confederations, etc.)	Income and expenditure of nonprofit sector/*special surveys*		Employment in nonprofit sector; wages in nonprofit sector/*special surveys*	

bodies that affect them. Usually those records fall into five categories: tax related, social insurance, engineering records on the performance of physical production, personnel and safety records, and environmental records if the productive activity is of sufficient importance and of a kind that may detrimentally affect the physical environment. The efficiency of statistical surveys is measured partly by the ability of the statistical agency to request that information, but mostly by that information which is readily available from the records the business tends to keep anyway.

Household Surveys

Usually the major surveys addressed to households include a survey of households and how their members relate to the labor force and a survey of family income and expenditure. The former is the basis upon which statistics on the percentage of the labor force that is unemployed are calculated. The latter usually produces two key statistics: income distribution and structure of household expenditure. The structure of household expenditure is used to determine the various proportions of expenditure, which in turn are used in the compilation of the consumer price index. The surveys about household behavior – variation in the structure of expenditure and savings according to income, location of residence, family size, and age distribution – also provide key social statistics.

Public Accounts and Administrative Records

There are at least two categories of records that make explicit survey taking redundant: (1) reports on public accounts and (2) administrative registers created as a result of regular and comprehensive administrative procedures. The two have different properties. The accounts of the public sector (and of parastatal enterprises such as nationalized industries or public corporations) are usually made available to the public as a means of displaying transparency and accountability. If the statistical requirement is limited to the displaying of aggregate information, what is published is usually sufficient as a description of the income, expenditure, and balance sheet of all public sector entities. In addition, all operations relative to the collection of taxes generate comprehensive records, susceptible to replace statistics to the extent the administrative registers target the same variables. For example, the collection of income tax generates statistics on the income structure of all households (or individuals) liable to pay tax. The collection of VAT-type taxes generates records on the amount of sales, the nature of the seller, and in many cases the broad economic sector to which the buyer belongs. Social security records tend to generate information on the nature of the workers from whom amounts for social insurance are withheld; their place of work; the hourly, daily, or weekly remuneration that serves as a basis for the estimation of the amount withheld; and so on. And of course, the oldest and most universal administrative operation of all – that connected with the activity of customs administrations – generates comprehensive information on the value, composition, conveyance used, origin, and destination of merchandise that either enters or leaves the national territory. This information, also known as merchandise exports and import statistics, is to be found among the earliest collections of numerical data of relevance to the administration of a country. To the extent that these administrative records are accessible to the compilers of statistics they tend to constitute acceptable replacements for estimates derived from surveys or from censuses.

Economic Classifications and Conceptual Frameworks

Standard Economic Classifications

Economic statistics – like any other kind of descriptive statistics – are usually presented within the framework of standard classifications. In addition to geographic classifications, the most popular of these classifications are the Standard Industrial Classification (the SIC, or in its international version, the ISIC) and the Standard Product Classification (the SPC or, in its international version, the Standard International Trade Classification or currently the Central Product Classification). The SIC refers to the activity (or production technique) used to produce a specified list of goods and services. Similar (or homogeneous) production techniques are grouped into industries. The overall result of these groupings is a classification that views economic activity from the supply side. The SPC groups goods and services by their intrinsic characteristics rather than by the way in which they were produced. It is a classification that views the results of economic activity from the demand side. The use of international classifications is vital to ensure intercountry comparability of economic statistics.

The history of international cooperation in economic statistics is inextricably bound with the history of the two major economic classifications. Thus, the United Nations Statistics Commission, at its first meeting immediately after the end of World War II, commissioned the Secretariat to produce a classification of economic activities and shortly afterward requested the development of a classification of the goods that entered into international exchanges (imports and exports). The Committee on Statistics of the League of Nations had worked on an initial version of such a classification. Almost immediately after the war the Statistics Commission approved the International Standard Industrial Classification of Economic Activities (ISIC) and the Standard International Trade Classification (SITC). Today, both classifications are into their fifth or fourth version (ISIC Rev. 4 and SITC Rev. 3, respectively).

Currently, the economic statistics of the members of the European Union and of many central and eastern European countries are classified by the NACE (Nomenclature des Activités économiques dans les Communautés Européennes). The three North American countries have their own system of economic classifications (North American Industrial Classification System – NAICS). Most other countries use one or another of the various versions of the ISIC.

The classification of goods was taken over by the body created to coordinate the activities of customs administrations worldwide (the Customs Co-ordination Council or since 1994 the World Customs Organization) and ended up as the Harmonized Commodity Description and Coding System (HS). As such it has been adopted for international trade statistics by the overwhelming majority of countries. Indeed, a number of them use the same classification for purposes of presenting their

commodity output in the context of their industrial statistics. The requirement to develop an international classification of services prompted – again at the request of the United Nations Statistical Commission – the development of the Central Product Classification (CPC), which is being increasingly used to compare statistics on international trade in services with the internal production of and commerce in services.

Other Classifications

These apply to a variety of economic statistics but they (with the possible exception of the International Standard Classification of Occupations) are neither as well developed as the ones on activity and product nor are they at this stage the subject of international agreement. There are several examples of such classifications. In the case of capital assets there is still the question of whether a classification of assets ought to be embedded in the standard classifications of goods or whether it should be *sui generis*. There is no suitable classification of intangible assets. In the realm of labor inputs, recent innovations in the contractual relationship between employers and employees have produced a variety of forms of employment, none of which has so far found its way into an accepted classification.

Conceptual Frameworks

The conceptual framework for economic statistics is a hybrid, somewhere between business accounting and the system of national accounts. But, because economic statistics are the prime ingredient for the compilation of the national accounts, an explicit reconciliation between the former and the latter is required. Current trends suggest that because of pressures to keep government-generated paperwork down, economic statistics tend to follow the patterns of business records, where required, supplementary information is collected so that the basic statistics may be reconciled to the requirements of the national accounts compilers. But typically the necessary adjustments are conducted within the statistical agency. This is usually the case for key balances such as profits.

The Evolution of Economic Statistics as a System

The traditional manner in which economic statistics were derived was by the periodic taking of an economic census. Indeed in earlier times the census of population was taken together with the economic census. More recently, the economic census is addressed at businesses and retrieves information on their activity, location, legal form of organization, and on how many and what kind of people they employ. Supplementary information is usually obtained through lengthier questionnaires addressed not to all businesses but rather to a selection, usually above a certain size but sometimes to a randomly selected fraction of all those in the scope of the census.

Censuses and Registers

Economic censuses have become steadily less popular, largely due to their cost, the time it takes to process them, and the fact that, because of rapid changes in the size, makeup, and even activity of businesses, census information loses much of its value shortly after it is compiled (*see* Statistical Systems: Censuses of Population). Instead, there has been an equally steady increase in the popularity of registers of businesses, usually derived from administrative data and used for much the same purposes as censuses but updated far more frequently. Indeed, in a number of cases, the introduction of new administrative procedures connected with tax gathering has been managed bearing in mind possible requirements of importance to the government's statistical agency.

The lists of businesses derived from administrative or tax-gathering procedures, commonly referred to as 'business registers,' are used mostly in two modes: as sampling frames and as a basis for indicators of economic performance such as 'net business formation' (the difference between the numbers of businesses created and the number of businesses closed down in a given period of time). As sampling frames, business registers are invaluable to support ad hoc inquiries into the state of the economy, usually conducted by contacting a randomly chosen group of businesses and gauging the opinion of their chief executive officers.

There are several requirements that must be satisfied for the modern approach to the compilation of business statistics to work. In particular, the source of information for the register must be comprehensive; it must be kept up to date as a result of the administrative procedures on which it is based; and the statistical agency must have unrestricted access to the source. The benefits that accrue to a statistical office from a business register are that: (1) it can dispense with the task of conducting a periodic census; (2) it can conduct a coherent set of sample surveys and link the resulting information so as to form a composite picture of the economy and its performance; and (3) it can control the paper burden that it imposes on individual business respondents through its multiple surveys.

Applications of Business Registers

Business registers are maintained at two distinct levels. There is a list of all businesses through their registration with some government department (usually the tax authority). This list conveys no more than there is a possible business behind a tax account. The physical counterpart of the tax account is usually determined by direct contact once it is established that the business is more than just a legal entity. The relationships between businesses as legal entities and the establishments, mines, mills, warehouses, rail depots, etc., that comprise them are a source of interesting information, but they are also the most difficult part of the management of a business register.

Current Economic Indicators

Under the impulse of macroeconomic stabilization policies and the belief in policy makers' ability to fine tune effective demand, the early 1960s saw a worldwide push to develop current economic indicators of demand by sector. A great deal of the empirical work had been done in the United States, spearheaded by the National Bureau of Economic Research and resulting in a classification of short term economic statistics

according to whether they lead, coincided, or lagged behind the 'reference' economic cycle. Most attention was placed on the performance of manufacturing industry, particularly on the output of equipment for/of fixed investment as well as for export; on the construction of plant and of other nonresidential structures; and, in general, on leading indicators of capital formation. At the same time considerable effort was made to improve the reliability and the timeliness of the key variables for purposes of economic stabilization: the rate of unemployment and the change in the consumer price index. Lastly, the balances in the main markets of the economy were looked at through quarterly national accounts, which in turn demanded major developments in the quality and the quantity of basic economic statistics.

Today's Array of Economic Statistics

In today's array of economic statistics the following would be the expected components in the more advanced statistical agencies: (1) statistics on the structure of the economy derived from either an economic census or from administrative data complemented by a survey on structural data (type of activity, breakdown of production costs, capital stock etc.); (2) exports and imports of goods and services, with the goods part broken down by commodity, country of origin, and destination; (3) producer and consumer prices and indexes thereof; (4) short-term indicators of economic change such as order books, deliveries of manufacturing goods, and stocks thereof; (5) monthly physical output of key commodities and an index of industrial production; and (6) business balance sheets (income, profit and loss, financial) and employment and unemployment as well as household income and expenditure. In addition, a statistical version of the accounts of the public sector would be an expected component.

In order to support these statistics, statistical agencies would maintain an up-to-date version of a classification by economic activity, usually an internationally agreed classification with a national supplement, and a classification of goods and services. They would also have their own or an international version of the classification of occupational employment.

Comparability and the Role of Eurostat

The creation and subsequent development of a statistical agency within the offices of the European Union meant a big step forward in the international comparability of economic statistics. For reasons connected with the administration of European community matters, member countries demand that there be common standards, terminology, classification, quality levels, and above all a verified level of compliance by all member countries with each of these. As a result, the adoption by the Union of new classifications and standards has meant that member countries follow suit albeit with short lags between the acceptance of the standard and its implementation. More importantly, never has so much attention been paid to national compliance with international statistical standards. Moreover, other countries either because they are candidates for admission to the Union or else because they are linked to Union members by economic ties, have also shown willingness to conform to the Union's classifications of economic activities, goods and services, methods of compiling price indices, and other important components of the structure of economic statistics. It would seem that we are about to enter an era in which lack of international comparability is no longer a principal challenge. What is looming large is the need for a capacity to incorporate rapidly in one's system of economic statistics, new ways of engineering and delivering services, new business organizations, and new forms of articulating the demand in one country with the supply in its trading partner.

Abstract

Statistical systems in the field of education provide data on student learning outcomes, student enrollment, education expenditures, and educational equality. The article describes the scope, methods, and basic results of some of the most influential programs developed by the Organisation for Economic Co-operation and Development – OECD (such as Program for International Student Assessment – PISA) and the International Association for the Evaluation of Educational Achievement (such as Third International Mathematics and Science Study – TIMSS and Progress in International Reading Literacy Study – PIRLS), as well as education databases developed by the World Bank and UNESCO. Specific results on educational equality are presented alongside critiques of large-scale student outcome assessments from a methodological and governance perspective.

Introduction

Since the formation of the Programme for International Student Assessment (PISA) by the Organisation for Economic Co-operation and Development (OECD) in 1997, education statistics have gained enormous recognition in science, in the general public, and in the policy world. Different sources for data on education exist on the national level, such as censuses, administrative records, and ministry of education records. But doubts about the effectiveness of education systems in many Western countries, such as the United States in the 1980s (Gardner et al., 1983), have sparked an interest in international education statistics. International organizations have addressed the demand for comparable education data and indicators by developing specialized statistical systems in the field of education. These statistical systems provide information about learning outcomes such as student skills or competencies at different grade levels and school types (PISA, TIMSS, PIRLS). They also report on student demographics (enrollment), education expenditure (World Bank Education Expenditure Database), and education equality in different countries (e.g., Demographic and Health Surveys (USAID), Monitoring the Situation of Children and Women (UNICEF), Living Standards Measurement Study (The World Bank)).

Learning Outcome Statistics

The two most influential organizations involved in the provision of statistical systems on student achievement are the Organisation for Economic Co-operation and Development, founder of the Programme for International Student Assessment (PISA), and the International Association for the Evaluation of Educational Achievement (IEA), best known for its Third International Mathematics and Science Study (TIMSS).

Growing concerns about the effectiveness of educational systems in Western countries, as well as increasing awareness of economic competitiveness in a global market led to a strong interest in comparative education statistics. The OECD responded to this demand by initiating the Indicators of Education Statistics (INES) program in 1987. To improve the quality of international education statistics, countries such as the Netherlands, Scotland, the United States, and Sweden contributed resources and brought together working groups of education practitioners and scholars to develop indicators such as enrollment in education, finance, learning outcomes, labor force outcomes, school functioning, and attitudes toward education. The first report was published as Education at a Glance: OECD Indicators in 1992. The INES working group members quickly became aware of the lack of coherent data for indicators on student achievement, which led to the establishment of PISA. The OECD launched its first PISA report in 2001 with a periodicity of 3 years. PISA covers 34 OECD member countries and 31 partner countries (2012), representing more than 80% of the world economy. PISA 2012 is the program's fifth survey. It assessed the competencies of 15-year olds in reading, mathematics, and science (with a focus on mathematics) in 65 economies. In 44 of those economies, about 85 000 students also took part in an optional assessment of creative problem solving, which measures students' skills to respond to nonroutine situations needed to achieve their potential as constructive and reflective citizens.

Since PISA seeks to understand how well schools prepare students for challenges in the future, it analyses basic knowledge, skills, and attitudes that are important for young adults to take part in social life as responsible citizens. The first of the four identified basic skills is reading literacy, which was the main focus of the PISA 2000 study. The reading literacy test analyzes to what extent adolescents are able to understand and integrate texts they are confronted with in their everyday lives. Reading literacy is defined as "understanding, using and reflecting on written texts, in order to achieve one's goals, to develop one's knowledge and to participate in society" (OECD, 2003: 108). Mathematical literacy is defined as "an individual's capacity to identify and understand the role that mathematics plays in the world, to make well-founded judgements and to use and engage with mathematics in ways that meet the needs of the individual's life as a constructive, concerned and reflective citizen" (OECD, 2003: 24). "Scientific literacy is the capacity to use scientific knowledge, to identify questions and to draw evidence-based conclusions in order to understand and

help make decisions about the natural world and the changes made to it through human activity" (OECD, 2003: 133). And finally problem solving is defined as "an individual's capacity to use cognitive processes to confront and resolve real, cross-disciplinary situations where the solution path is not immediately obvious and where the literacy domains or curricular areas that might be applicable are not within a single domain of mathematics, science or reading" (OECD, 2003: 156).

Around 510 000 students between the ages of 15 years 3 months and 16 years 2 months participated in PISA 2012, representing about 28 million students globally. Students took a paper-based test that lasted 2 hours. The tests were a mixture of open-ended and multiple-choice questions that were organized in groups based on a passage setting out a real-life situation. School principals also answered questionnaires to provide information about the student and teacher body (grade levels, student enrollment, staff size), the school's resources (location, public or private, funding), the school's instruction, curriculum, and assessment (ability grouping, extracurricular activities, forms of student performance assessment), the school climate, the school policies and practices (assessment data, monitoring practices), and the characteristics of the principal (gender). Although most public attention was paid to student performance data, the study also provided data on instructional settings (student perception of class climate and teacher support), on educational service providers (school resources, admittance, and grouping), as well as system-level aggregated data on the educational system as a whole, which were based on the context questionnaires.

According to the results of the latest PISA in 2012, China has the highest scores in mathematics, with a mean score of 613 points, which is 119 points, or the equivalent of nearly 3 years of schooling, above the OECD average. Singapore, Hong Kong-China, Chinese Taipei, Korea, Macao-China, Japan, Liechtenstein, Switzerland, and the Netherlands, in descending order of their scores, round out the top ten performers in mathematics. Of the 64 countries and economies with trend data between 2003 and 2012, 25 improved student performance in mathematics. Boys perform better than girls in mathematics in only 38 out of the 65 countries that participated in PISA 2012, and girls outperform boys in five countries. Across OECD countries, 13% of students are top performers in math.

Shanghai-China, Hong Kong-China, Singapore, Japan, and Korea are the five highest performing countries and economies in reading. Of the 64 countries with comparable data throughout their participation in PISA, 32 improved student performance in reading. Across OECD countries, 8% of students are top performers in reading. These students can handle texts that are unfamiliar in either form or content and can conduct fine-grained analyses of texts.

Shanghai-China, Hong Kong-China, Singapore, Japan, and Finland are the top five performers in science. Between 2006 and 2012, Italy, Poland, and Qatar, and between 2009 and 2012, Estonia, Israel, and Singapore increased their shares of top performers and simultaneously reduced their shares of low performers in science. Across OECD countries, 8% of students are top performers in science. These students can identify, explain, and apply scientific knowledge in a variety of complex life situations.

Students in Singapore and Korea, followed by students in Japan, score higher in problem solving than students in all other participating countries and economies. Boys outperform girls in problem solving in 23 countries/economies, girls outperform boys in five countries, and in 16 countries, there is no significant difference in average performance between boys and girls. The impact of socioeconomic status on problem-solving performance is weaker than it is on performance in mathematics, reading, or science. Across OECD countries, 11.4% of 15-year-old students are top performers in problem solving.

The IEA's TIMSS study has been carried out every 4 years since 1995. Its area of coverage in 2011 included 63 countries, plus 14 benchmarking entities (regional jurisdictions such as Abu Dhabi or Quebec). The TIMSS countries vary greatly in terms of economic development, geographical location, and population size. TIMSS provides an international assessment of mathematics and science at the fourth and eighth grades. The content domains (for example, algebra, geometry, etc. in mathematics, and biology, chemistry, etc. in science) and the topic areas within the domains are described separately for the fourth and eighth grades in the TIMSS 2011 Mathematics Framework and the TIMSS 2011 Science Framework. TIMSS explains its focus on mathematics by stating that "effectiveness as a citizen and success in a workplace are greatly enhanced by knowing and, more important, being able to use mathematics" (Mullis et al., 2012b: 20). Similarly the authors point out that "in today's world, some understanding of science is imperative if citizens are to make informed decisions about themselves and the world in which they live" (Mullis et al., 2012b: 49). Nationally representative samples of students participated in TIMSS. Countries and benchmarking participants could elect to participate in the fourth grade assessment, the eighth grade assessment, or both: Fifty-two countries and seven benchmarking entities participated in the fourth grade assessment, and 45 countries and 14 benchmarking entities participated in the eighth grade assessment. Several of the countries, where fourth and eighth grade students were expected to find the TIMSS assessments too difficult, administered the fourth and eighth grade assessments to their sixth and ninth grade students. In total, more than 600 000 students participated in the 2011 TIMSS.

The TIMSS 2011 mathematics framework is organized around two dimensions: (1) a content dimension specifying the domains or subject matter to be assessed within mathematics (for example, number, algebra, geometry, and data and chance at the eighth grade) and (2) a cognitive dimension specifying the domains or thinking processes to be assessed (that is, knowing, applying, and reasoning). The cognitive domains describe the sets of behaviors expected of students as they engage with the mathematical content (Mullis et al., 2012b: 19).

Fourth graders from East Asian countries continue to lead the world in mathematics achievement. Singapore, Korea, and Hong Kong SAR, followed by Chinese Taipei and Japan, Northern Ireland, Belgium (Flemish), Finland, England, and the Russian Federation were the top 10 performing countries at the fourth grade level.

At the eighth grade level, Korea, Singapore, and Chinese Taipei outperformed all other countries, followed by Hong Kong SAR, Japan, the Russian Federation, Israel, Finland, the United States, and England and were the top 10 performing countries. While small differences appeared from country to

country, there was a substantial range in performance from the top performing to the lower performing countries. The 22 countries assessing fourth grade students and the three assessing sixth grade students displayed average achievement levels below the TIMSS scale centerpoint of 500, as did two benchmarking participants. At the eighth grade level, 27 countries and the three assessing their ninth grade students had average achievement below 500, as did three benchmarking participants.

IEA and the TIMSS and PIRLS International Study Center at Boston College launched another international program, the Progress in International Reading Literacy Study (PIRLS). PIRLS reports on primary school students' literacy achievement in 49 countries every 5 years. Reading literacy is defined as "the ability to understand and use those written language forms required by society and/or valued by the individual. Young readers can construct meaning from a variety of texts" (Mullis et al., 2003: 33). In 2011, PIRLS also examined national policies and practices related to literacy, and included a set of questionnaires for students, parents/caregivers, teachers, and school principals to investigate the experiences that young children have at home and school while learning to read. In 2011 for the first time, pre-PIRLS offered assessment of basic reading skills, working as a bridge to PIRLS. Especially for countries where most children are still developing basic reading skills at the end of the primary school cycle. PIRLS targets fourth grade students. In 2011, 49 countries and 9 benchmarking entities participated in PIRLS and pre-PIRLS. Approximately 325 000 students participated in the 2011 cycle.

Recent studies based on TIMSS and PIRLS data from 34 participating countries in 2011 show positive correlations among reading, mathematics, and science achievement at the fourth grade. More than 50% of the 34 participating countries succeeded in educating 90% or more of the fourth grade students to a basic level of proficiency in all three subjects. The study also demonstrated educational practices of effective schools, teachers, and parents to ensure student achievement (Martin and Mullis, 2013). The TIMSS and PIRLS model of educational practices in effective schools includes being safe and orderly, supporting academic success, having adequate facilities and equipment, being well-staffed with well-prepared teachers, and providing well-resourced classrooms and effective instruction (Martin and Mullis, 2013: 113).

The third international statistical system provided by IEA is the International Civic and Citizenship Education Study 2009, which is the third IEA study (after 1971 and 1999) on civic and citizenship education. The study reported on the achievement of students enrolled in the eighth grade in a test of knowledge and conceptual understanding, along with student dispositions and attitudes relating to civics and citizenship (Schulz et al., 2010). Teacher and school questionnaires collected information about the contexts in which students learn about civics and citizenship, including teaching and classroom management practices, and school governance and climate. Earlier studies (Torney-Purta et al., 2001) highlighted that students who participated in governance and decision-making of their schools score higher in civic knowledge and engagement scales. Therefore the degree of student and teacher involvement in decision-making processes and practices about the way classes are taught, what is taught in classes, teaching and learning materials, timetable, classroom and school rules at their respective schools were part of the questionnaire. National context surveys asked about the provision of civic and citizenship education in each participating country. The data collection took place in 38 countries between 2008 and 2009. The studies provided a concept of civic education, which was not limited to the basic knowledge about the inner workings of political systems, but was aiming at educating citizens which are able to participate in democratic societies. IEA therefore described civic education as follows: "According to the information collected from the ICCS national research centers, civic and citizenship education covered a wide range of topics across the participating countries. These encompassed knowledge and understanding of political institutions and concepts, such as human rights, as well as newer topics covering social and community cohesion, diversity, the environment, communications, and global society. Most teachers and school principals regarded the development of knowledge and skills as the most important aim of civic and citizenship education" (Schulz et al., 2010: 251).

Criticism

Since its formation, the PISA program has sparked international controversy among scholars and policy makers about the use of standardized learning outcome data for evaluating the quality of schools. Critics raise methodological questions on the study's lack of longitudinal data (Fertig, 2003), its lack of comparability (Blum et al., 2001), the nature of the test questions (Prais, 2003; Bonnet, 2002), issues of translating standardized questions in different cultural contexts and languages, and in more general terms a decontextualization of student outcome data in an attempt to compare educational systems worldwide (Wuttke, 2006; Spiegelhalter, 2013). Age differences of up to 2 years are problematic for international data comparability in all grade level studies. The representativeness of national samples and test-wiseness of pupils in different countries can also be highly problematic in biasing differences across countries (Wuttke, 2006). General competency tests in student assessment surveys have strong similarities with intelligence tests. In order to get at cultural competencies, the test would need to include more knowledge-based items (Rindermann, 2007).

Others criticize the policy implications of the study, such as its 3-year cycle, which has shifted policy makers' attention to short-term fixes (Andrews et al., 2014) instead of long-term improvement of national education systems. The narrow focus on measurable education outcomes also undermines the importance of less measurable aspects of education, such as moral, physical, civic, and artistic impacts (Ertl, 2006), which are related to the controversial debate on outcome-centered governance in education (Soquel and Jaccard, 2008). In terms of data validity, scholars criticize the isolation of student assessment studies from other related research such as empirical studies on the intelligence construct or economic human capital research (Rindermann, 2007). Finally scholars find that research on causes for different national competency levels is still in its infancy. There are likely to be complex reciprocal influences between educational, genetic, economic, political, and cultural factors (Rindermann, 2007).

Education Equality, Education Expenditures, and Student Demographics

The big education statistical systems – TIMMS, PIRLS, and PISA – as well as big international surveys by USAID, UNICEF, and The World Bank also provide Education Equality Data. Since 1984, USAID's demographic and health surveys (DHS) have conducted nationally representative household surveys (in over 80 countries) to provide data for a wide range of monitoring and impact evaluation indicators in the areas of population, health, and nutrition, but also on the situation of women and gender differentials in the area of education. Standard DHS sample up to 30 000 households and are conducted about every 5 years. Interim DHS are conducted between rounds of the standard surveys and provide additional, representative data. While clearly focusing on health topics, all demographic and health surveys include DHS indicators about gender differences in literacy, educational attainment, and education based on the idea that education is the key to empowering women.

The second important source of education equality data is the Monitoring the Situation of Children and Women Survey (UNICEF). In 1995, UNICEF began supporting countries for the collection of statistically sound and internationally comparable data through Multiple Indicator Cluster Surveys (MICS). Data are gathered from two sources: enrollment data from administrative records, and attendance data from household surveys. After four rounds of MICS, 240 surveys have been conducted in more than 100 countries. The surveys consist of a household questionnaire, a questionnaire for women aged 15–49, a questionnaire for individual men aged 15–49, and a questionnaire for children under the age of five (administered to the mother or caretaker). Together, they help measure key indicators on households, and life circumstances of women, men, and children. Seen as vital to meeting the Millennium Development Goals, UNICEF collected data about universal primary education, gender disparities at all levels of education, and the empowerment of women. In addition to that, UNICEF gathered administrative data on school participation, youth and adult literacy rates, survey data on primary net attendance rate, primary survival rate, and secondary net attendance rate.

In 1980 the World Bank's Development Research Group (DECRG) established the Living Standards Measurement Study (LSMS) exploring ways of improving the type and quality of household data collected by statistical offices in developing countries. LSMS includes data sets from 37 countries (from Albania to Vietnam), the earliest surveys dating back to 1985. LSMS aimed to help policy makers move beyond simply measuring rates of unemployment, poverty, and healthcare use, by assisting them in their efforts to identify how they could design and improve policies that positively affect outcomes in health, education, economic activities, housing, and utilities. LSMS surveys intend to produce a comprehensive monetary measure of welfare and its distribution, describe patterns of access to and use of social surveys, and allow the study of how households behave in response to changes in the economic environments or government programs. Therefore the LSMS has created a database of harmonized variables from LSMS surveys to facilitate comparative research. LSMS covers various topics. The household questionnaire includes measures of consumption, measures of income, and a variety of sectoral issues, such as health, education, nutrition, and fertility. The community questions describe the economic environment faced by the households in the sample. The prices questionnaires gather information on prices of basic goods in the communities. In some countries special questionnaires are used for schools (Grosh and Munoz, 1996). The LSMS website lists research reports and publications, including LSMS working papers, based on the collected data sets.

Social Background, Gender, and Education Equality

PISA data across OECD countries suggest effects of socioeconomic situation of students on their learning outcome. A student's socioeconomic status is estimated by the PISA index of social, cultural, and economic status, which is based on indicators such as parental education and occupation, the number and type of home possessions that are considered proxies for wealth, and the educational resources available at home. The PISA consortium claims that across OECD countries, 14.8% of differences in performance among students are explained by disparities in students' socioeconomic status, whether the focus is on mathematics, reading, or science. PISA data suggest that a more socioeconomically advantaged student scores 39 points higher in mathematics – the equivalent of nearly 1 year of schooling – than a less-advantaged student (OECD, 2014b: 34). On the other hand, some 6% of students across OECD countries appear 'resilient' to socioeconomic disadvantages and exceed expectations.

Integrating immigrant students into the education system is a challenge for most countries; however a country's success in integrating immigrants' children into society is a key indicator of the efficacy of education policy. In OECD countries, immigration status is still linked to educational disadvantage. While the share of immigrant students in OECD countries increased from 9% in 2003 to 11% in 2012, their performance disadvantage as compared to students without an immigrant background but with similar socioeconomic status shrank by 11 score points during the same period, which indicates a decreasing level of disadvantages for students with immigration status. Overall 'immigrant students' performance in PISA is more strongly (and negatively) associated with the concentration of socioeconomic disadvantage in schools than with the concentration of immigrants per se or the concentration of students who speak a different language at home than the one in which they are taught at school. Reducing the concentration of disadvantage in schools may require changes in other social policy, such as housing or welfare, to encourage a more balanced social mix in schools (OECD, 2014b: 71).

PIRLS data show significant gender differences in reading competencies with the exceptions of Luxemburg and Spain. All participating countries show higher reading competencies for boys (on average a 17 point difference), which holds for both analyzed text categories (literature and information). The gap between girls and boys is higher for upper level reading skills such as interpret, connect, and evaluate than for base level skills such as repetition and simple conclusion (Mullis et al., 2012a). In most countries and economies, boys outperform girls in

mathematics; and among the highest achieving students, the gender gap in favor of boys is even wider.

Education Expenditures and Student Demographics

The World Bank Education Expenditure Database and the UNESCO Institute for Statistics provide data on education expenditures as a percentage of total government spending, as a percentage of GDP and government expenditure per student, and by level of education. In 2002, the World Bank Education Expenditure Database started collecting data from public expenditure documents across 97 countries, using 891 indicators. However, such data are not internationally comparable since there is no standard method of calculation for most of the indicators. As a result, cross-country comparisons are not advisable.

The UNESCO Institute for Statistics also publishes a Global Education Digest, which includes public expenditure data on education based on three questionnaires (UIS, UOE, and WEI), from 204 countries and territories. The main issues regarding student demographics pointed out by the Global Education Digest 2012 are high numbers of about 32 million primary pupils repeating grades, and 31 million students completely dropping out of school. These numbers are alarming because UNESCO asserts that once pupils drop out of school, most never return. Eighty percent of those children live in only three world regions. Sub-Saharan Africa with four, South and West Asia with three, and Latin America and the Caribbean with two dropouts for every 10 children who start school. While girls are less likely to start school in the beginning, boys more often tend to leave school before even completing primary education, and more often repeat grades. The overall gap between boys and girls remains wide. In 2011, an estimated 31 million girls of primary school age and 34 million girls of lower secondary school age were not enrolled in school at all. In addition, pupils from rural households are much more likely to repeat a grade.

Significant regional differences are also demonstrated for reading literacy: the "SACMEQ (2007) assessment conducted in 14 sub-Saharan African countries show that in about one-half of countries pupils at the end of primary school had low performance levels in reading. In Malawl and Zambia. Almost three in four tested pupils were unable to meet minimum requirements for reading. […] A range of data sources show that children with the least opportunities – arising from poverty and compounding disadvantages – are most likely to repeat grades and leave school early without being able to read a basic text." (UNESCO, 2012: 47).

PISA data indicate how disparities in exposure to formal mathematics are more marked in school systems that separate students into different schools based on their performance. The strong relationship between performance and socioeconomic status was again demonstrated in systems where the unintended result of separation by performance is separation by socioeconomic status. PISA data also emphasize the importance of early childhood education, because many inequities that exist within school systems are already present when students enter formal schooling. Earlier entrance into the school system might prepare students better to succeed in formal schooling and therefore might help to prevent some inequities. PISA claims that across OECD countries, students who reported that they had attended preprimary school for more than 1 year score 53 points higher in mathematics (equivalent of more than 1 year of schooling) before accounting for socioeconomic status, and 31 points after accounting for socioeconomic status, than students who had not attended preprimary education (OECD, 2014b: 99). These data suggest that early attendance in preprimary education is positively correlated with socioeconomic status; however it also suggests a positive correlation between preprimary school attendance and performance at age 15 or 16, which is independent of socioeconomic status (OECD, 2014b: 99).

Both PISA and TIMSS data suggest that teacher shortage is an issue in socioeconomically disadvantaged schools. OECD countries allocate at least an equal, if not a larger, number of teachers to socioeconomically disadvantaged schools as to advantaged schools; but disadvantaged schools tend to have great difficulty in attracting qualified teachers (OECD, 2014b: 14).

TIMSS/PIRLS data show that successful schools tend to be well resourced. Ever since the Coleman report in 1966, researchers have recognized that the compositional characteristics of a school's student body can affect student achievement. To provide information on this topic, TIMSS routinely asks school principals to report on their students' economic home backgrounds and home language. While there was variation across countries, higher average mathematics achievement was associated with students attending schools where a greater percentage of students were from relatively affluent socioeconomic backgrounds and spoke the language of the TIMSS assessment as their first language (Mullis et al., 2012b: 205).

Overall successful schools also are likely to have better working conditions and facilities as well as more instructional materials, such as books, computers, technological support, and supplies. TIMSS 2011 created the Mathematics Resource Shortages scale based on principals' responses concerning inadequacies in general school resources (materials, supplies, heating/cooling/lighting, buildings, space, and staff) as well as resources specifically targeted to support mathematics instruction (specialized teachers, computers, computer software, calculators, library materials, and audio-visual resources). Many countries were fortunate to have very few students in schools where instruction was affected a lot by resource shortages. However, this was a crucial problem in some countries. At both the fourth and eighth grades, the one-quarter of students in schools not affected by resource shortages had higher average mathematics achievement than their counterparts in less well-resourced schools. For students at the sixth and ninth grades, there was more impact from lack of resources, with greater percentages of students in schools affected a lot by resource shortages (Mullis et al., 2012b: 229).

Conclusion

Increased public and policy demand in the 1980s for data to compare educational systems among different countries has advanced the field of international education statistics. International organizations such as the OECD and the IEA have created organizational structures for collaboration among

educational professionals, policy makers, and statisticians from different countries, which engaged in the development of shared definitions, concepts, indicators, and methodologies to ensure comparability of results across a wide variety of countries. Statistical systems in education today provide data on student learning outcome for different grade levels and subject areas (including mathematics, reading, science, and civic education), participation in education, education expenditures, and educational equality.

Statistical systems in the field of education not only provide academic knowledge and public information, but have also gained influence in the governance of education. Corresponding to outcome orientation in New Public Management (Nutley and Boaz, 2003), student learning outcome data have become part of public debate on education policy and governance. The indicators in statistical systems in the field of education played an important part in constructing a global policy field through governance by comparison (Martens, 2007). Competitiveness is increasingly used as a strong argument in various national legitimation strategies for education reform. Because the OECD and IEA frame student learning outcome data as indicators of the performance of education systems, they have become a factor in the international trend toward 'governing by numbers' or 'the politics of comparison' in the field of education (Grek, 2009). Yet, despite the effort and resources devoted to the high standards and quality control of those systems, scholars still question the methodological validity of international large-scale surveys on student assessments (Rindermann, 2007).

Data Bases and Statistical Systems: Education, Statistical Systems

Tom Snyder, Chantilly, VA, USA

Published by Elsevier Ltd.

Abstract

Globalization of commerce has posed a need for more accurate and comprehensive international education comparisons, and this need has been met by new collections of international data and improvements to traditional education statistics. While many areas of international education comparisons remain problematic, advances in recent years provide important new information for policy makers and break new ground for further work by the research community. This article outlines new opportunities to make contributions to the area of international education statistics, and thus improve the information flow to policy makers and the public to make informed decisions on education processes. The data sets discussed in the article highlight modern education data collections available to the public that enable statistical comparisons among large groups of countries. While these data do not answer many research questions that can only be addressed by more detailed and specialized research studies, today's international data systems provide rich resources for understanding the differences in national education structures and targeting research efforts on specific promising developments.

The evolution of global communications has prompted major shifts in the operations of business and the exchange of information. While heavy and light industries have been affected by international trade for centuries, the intensity of sharing intellectual services across continents is a comparatively recent phenomenon. Corporations now routinely outsource computer programming, web design, accounting work, legal research, and a wide variety of other tasks to well-educated persons in foreign countries. Formerly, these high-paying positions were held by domestic employees. Now, retaining these highly skilled jobs has put pressure on countries and individuals to maintain high education standards to remain competitive in a market for highly skilled labor that is increasingly global.

While traditional metrics of productivity served well in measuring the output of individuals in an industrial setting, these measures are not adequate to measure the potential capacity of a population to engage in processes requiring relatively high intellectual inputs. In order to attract modern factories and support intellectual service enterprises, countries need to demonstrate the ability of their labor force to perform these skills. Countries and localities are finding it necessary to demonstrate the skills and educational backgrounds of their labor force through statistical data to attract new business or retain current ones. These businesses and their employees pay taxes that support government revenue and enable public services. In addition, higher levels of education have been consistently associated with higher income for individuals across countries. While manufacturing firms have long demonstrated the ability to transfer operations to areas with lower-cost labor, intellectual processing tasks now also can be transferred to other countries through simple contracting arrangements and advanced Internet-based communications. Thus, the international demand for intellectual skills and the growing fluidity of labor pools have increased the value and need for international education comparisons.

The need for more accurate and comprehensive international education comparisons has been met by new collections of international data and improvements to traditional education statistics. While many areas of international education comparisons remain problematic, the advances in recent years provide important new information for policy makers and break new ground for further work by the research community. This article is designed to outline new opportunities to make contributions to the area of international education statistics, and thus to improve the information flow to policy makers and the public to make informed decisions on education processes. The data sets discussed in the article highlight modern education data collections available to the public that enable statistical comparisons among large groups of countries. While these data do not answer many research questions that can only be addressed by more detailed and specialized research studies, today's international data systems provide rich resources for understanding the differences in national education structures and targeting research efforts on specific promising developments.

Developing International Comparisons

International education statistics have been available for decades through the efforts of the United Nations Educational, Scientific, and Cultural Organization (UNESCO) Institute for Statistics. Beginning in the 1960s, UNESCO worked on enumerating basic education statistics for all countries. The main efforts were to compile fundamental data on enrollments, degrees and certificates, teachers, and financial statistics. While coverage and timeliness were substantial challenges, the data represented the only comprehensive efforts in those years to compile comparable data for all countries in the world. By the early 1990s, it was clear that more detailed and timely data was needed by economically developed countries to provide statistical indicators on education on an ongoing basis. The Organization for Economic Cooperation and Development (OECD) was encouraged by the United States and other member countries to coordinate new data collection efforts that culminated in the first edition of *Education at a Glance* in 1992 (http://www.oecd.org/edu/skills-beyond-school/49338320.pdf). Later OECD and UNESCO data efforts were coordinated for OECD countries, since the data needs for the two international organizations overlapped to a large extent. Also, the needs for European Union as

represented by Eurostat were integrated into the data collection system. Through systematic efforts of OECD and member countries, as well as support from other international organizations, the collection of education data for OECD countries improved markedly during the following two decades. While data quality challenges remain, there have been notable strides in the coverage of education statistics collections and improvements in data quality and comparability. The administrative components of these data collections today include enrollments; student mobility from country to country; teachers; diplomas and degrees; education finance; labor force characteristics related to education; and system-level data on education structures. In addition, new assessments of students and adults provide information on the skill levels attained by individuals. Taken together, these data provide critical information on the basic characteristics of education systems, and are widely accessible to the public, through the annual *Education at a Glance* indicators report (http://www.oecd.org/edu/eag2013%20(eng)–FINAL%2020%20June%202013.pdf), published by OECD, and the periodic *World Education Indicators*, published by UNESCO. The results from these core data collections are also published by other international and national organizations and components of the raw survey data can be downloaded from UNESCO and OECD.

One of the key challenges in collecting and disseminating international education data is classifying levels of education in ways that are comparable from country to county. The current classification system of levels of education is called the International Standard Classification of Education, 1997, or ISCED 1997. A revised classification system ISCED 2011 has been approved for worldwide use, and was used in data collections beginning in early 2014. The data currently available were collected under the ISCED 1997 system, which is described in the accompanying text box.

International Standard Classification of Education (ISCED 1997)

ISCED Level 0 Education preceding the first level (early childhood education) usually begins at age 3, 4, or 5 (sometimes earlier) and lasts from 1 to 3 years.

ISCED Level 1 Education at the first level (primary or elementary education) usually begins at age 5, 6, or 7 and continues for about 4–6 years.

ISCED Level 2 Education at the second level (lower secondary education) typically begins at about age 11 or 12 and continues for about 2–6 years. Education at the lower secondary level continues the basic programs of the first level, although teaching is typically more subject focused, often using more specialized teachers who conduct classes in their field of specialization. The main criterion for distinguishing lower secondary education from primary education is whether programs begin to be organized in a more subject-oriented pattern, using more specialized teachers conducting classes in their field of specialization. If there is no clear breakpoint for this organizational change, lower secondary education is considered to begin at the end of 6 years of primary education. In countries with no clear division between lower secondary and upper secondary education, and where lower secondary education lasts for more than 3 years, only the first 3 years following primary education are counted as lower secondary education.

ISCED Level 3 Education at the third level (upper secondary education) typically begins at age 15 or 16 and lasts for approximately 3 years. Upper secondary education is the final stage of secondary education in most OECD countries. Instruction is often organized along subject-matter lines, in contrast to the lower secondary level, and teachers typically must have a higher level, or more subject-specific, qualification. There are substantial differences in the typical duration of programs across countries, ranging from 2 to 5 years of schooling. The main criteria for classifications are (1) national boundaries between lower and upper secondary education and (2) admission into educational programs, which usually requires the completion of lower secondary education or a combination of basic education and life experience that demonstrates the ability to handle the subject matter in upper secondary schools.

ISCED Level 4 Education at the fourth level (postsecondary non-tertiary education) straddles the boundary between secondary and postsecondary education. This program of study, which is primarily vocational in nature, is generally taken after the completion of secondary school and typically lasts from 6 months to 2 years. Although the content of these programs may not be significantly more advanced than upper secondary programs, these programs serve to broaden the knowledge of participants who have already gained an upper secondary qualification.

ISCED Level 5 Education at the fifth level (first stage of tertiary education) includes programs with more advanced content than those offered at the two previous levels, and is divided into 5A (academic) and 5B (vocational). Entry into programs at the fifth level normally requires successful completion of ISCED level 3 or ISCED level 4.

ISCED Level 5A Tertiary-type A programs provide an education that is largely theoretical and is intended to provide sufficient qualifications for gaining entry into advanced research programs and professions with high skill requirements. Entry into these programs normally requires the successful completion of an upper secondary education; admission is competitive in most cases. The minimum cumulative theoretical duration at this level is 3 years of full-time enrollment. ISCED 5A programs include not only bachelor's degrees, but also other degrees below the doctor's degree level, such as master's degrees.

ISCED Level 5B Tertiary-type B programs are typically shorter than tertiary-type A programs and focus on practical, technical, or occupational skills for direct entry into the labor market, although they may cover some theoretical foundations in the respective programs. They have a minimum duration of 2 years of full-time enrollment at the tertiary level. In the United States, such programs are often provided at community colleges and lead to an associate's degree.

ISCED Level 6 Education at the sixth level (advanced research qualification) is provided in graduate and professional schools that generally require a university degree or diploma as a minimum condition for admission. Programs at this level lead to the award of an advanced, postgraduate degree, such as a Ph.D. The theoretical duration of these programs is 3 years of full-time enrollment in most countries (for a cumulative total of at least 7 years at levels 5 and 6), although the length of the actual enrollment is often longer. Programs at this level are devoted to advanced study and original research (http://nces.ed.gov/programs/coe/glossary.asp#i, and http://www.uis.unesco.org/Education/Pages/international-standard-classification-of-education.aspx).

While the ISCED:97 overview serves well as guidance to researchers, more detailed reference documents are provided to country officials who are responsible for reporting national data according to these international guidelines. It should be noted that the ISCED structure was not intended to take into account the rigor of national programs or the curricular content, except in the most basic way (e.g., academic or vocational). While many education programs do correspond clearly into one of the ISCED levels, most countries have at least some programs that contain characteristics associated with two different ISCED levels, and these classification problems present at least some limitations in international comparability. One of the key limitations in the ISCED:97

structure was the lack of a specific classification of master's degrees programs. This presented difficulties for some countries, such as the United States, in the 1990s, but the problem expanded as a result of the 'Bologna Process' in Europe. Through the Bologna Process, many countries adopted the bachelor's/master's/doctor's structure similar to that used in the United States. The introduction of the classification for a master's level of education is one of the important improvements coming through the ISCED:11 classification system (*A New ISCED: Reflecting Today's Education Systems*, UNESCO, Institute for Statistics http://www.uis.unesco.org/Education/Documents/UNSD_newsletter_27e_ISCED.pdf).

The comprehensive international education statistics that are currently compiled on a routine basis are fundamentally based on two different structures of data collection. There are country-level data, primarily based on administrative records that usually are reported on an annual basis by country-level respondents to UNESCO, OECD, and Eurostat. The second type of data collection involves representative samples of individuals within countries. The most frequently encountered sample data of this type are student achievement data collected through the Trends in International Mathematics and Science Survey (TIMSS) and the Programme for International Student Assessment (PISA). There is also a new literacy assessment for adults entitled Programme for International Adult Competencies (PIAAC). These two general structures of international data collection are not completely distinct by original survey method since there are sample data compiled by countries and submitted as national summaries in conjunction with administrative data, and there are country-level data appended to the assessment data sets. Both the country-reported summary data and national samples each contribute important information about education programs and lead to a more complete understanding of national education systems.

Country-Reported Data

Data that are summarized at the country level and reported by county representatives are primarily based on administrative data collections conducted by the national education authorities. The annual data compiled by UNESCO, OECD, and Eurostat are collected through a set of survey instruments called the UOE. The data collected by UNESCO are the more basic and are requested for all UN countries. This data collection includes information on enrollments, staff, graduates, and finance. OECD countries are requested to report more detailed data, particularly on tertiary education, as well as data on educational characteristics of the labor force, and on operations of national education systems. European Union countries are required to report the OECD data, plus additional detailed information for Eurostat. Most of the data collected by UNESCO are publically available from reports and an online data tool. OECD publishes a comprehensive annual report entitled *Education at a Glance*, which highlights these data collections, plus other more specialized reports. Other key data can be downloaded from their web tool. Eurostat primarily releases data through reports, but also makes some data sets available through purchase.

Enrollment

The most basic data characterizing an education system are student enrollments. Since enrollment data are generally a component of education funding formula, they are often among the most accurate and consistently collected data. The enrollment survey is a fundamental component of the OECD UOE data collection. Enrollment data provide fundamental information on the scope of an education system, and trend data provide information on whether the system is growing or contracting. These changes in enrollment are a critical concern of policy makers because they affect budgetary considerations with respect to decisions on such topics as staff hires, school construction and renovations, and labor pool entry. Not only are enrollment data a key statistic on their own, but they are often used as a denominator in conjunction with other education data such as finance and teachers. Statistical measures such as expenditures per student and students per teacher provide metrics that control for the size of the education system. While enrollment data may be thought of as being very definitive in terms of concept and definition, there can be complexities in the classification of students, particularly at the postsecondary level, or between academic and vocational programs. Another element of potential data problems involves full-time and part-time students. The distinction between full-time and part-time enrollment can be important in ratios to finance and other variables that are optimally computed on the basis of full-time-equivalent students. The extent to which the full-time-equivalent of the part-time students can be calculated with precision can affect ratios based on these computations. Countries most often experience difficulties in computing full-time-equivalent enrollment at the preprimary and postsecondary levels. Despite some limitations, enrollment data are considered core information for understanding the scope of education systems and are frequently a key component of long-term trend analyses.

Staff

The annual collections of education data conducted by international organizations (UOE) focus on teachers, rather than on other types of school staff. Teacher counts often are gathered by characteristics, such as age, gender, and full-time/part-time employment status. There is also a separate data collection by the OECD on average salaries for teachers. Data are on other school staff such as teaching assistants and school level managers are collected annually through the UOE, with periodic collections of other staff. Two key metrics of particular interest to the research and policy-making communities are the pupil/teacher ratios and the average salaries for classroom teachers. The pupil/teacher ratio is a key measure of the teaching resources available in schools. The average teacher salary provides an indication of the financial value placed on hiring high-quality staff, particular when referenced to earnings metrics for other professions within the specific country. Thus, teachers' salaries are sometimes compared to GDP per capita, or earnings of other individuals with similar levels of education. Potential challenges in the use of teacher data, particularly in the use of ratios, are the determination of full-time-equivalent teachers based on counts of full-time and

part-time teachers. For many countries at the ISCED Levels 1–3, most teachers instruct full time so this is often not a serious problem. However, some countries do have large numbers of part-time teachers at the ISCED Levels 1–3, and many countries have relatively large numbers of part-time teachers at ISCED Levels 5 and 6. Also, the varying research duties and instructional loads for tertiary faculty can make comparisons at that level somewhat difficult to interpret.

Graduates

The counts of education-level graduates provide essential data on the output of an education system. When compared to enrollment or relevant-aged population groups, these data can provide comparisons of the proportion of students or population who are obtaining diplomas and degrees. Some measures of equity, particularly involving males and females are also feasible in most international data collections; however measures for economically or other types of at-risk populations are generally not available for most international data collections based on administrative data. Completions at the college level can be disaggregated by field of study to measure the relative output of graduates prepared for critical occupational areas. While data on school completions do not involve some of the limitations of full-time versus part-time status that enrollment data can present, the classification of programs at particular ISCED levels can present a problem. The general concept of high school or secondary (ISCED Level 3) is common across many countries, although some programs are longer or shorter in duration. However, the distinctions in academic and vocational programs can pose difficulties in comparisons. For example, Denmark, Germany, Austria, Iceland, and other countries have long duration ISCED Level 3 vocational programs that can last until students are 22, 23 years, or older. Programs at these levels may be classified as postsecondary in other countries. At the postsecondary, there are many types of vocational programs of varying lengths that are currently classified as ISCED Level 5B. Programs that are classified as postsecondary academic may range in length from 3 to 6 years of full-time study. The introduction of the ISCED 2011 classification structures will substantially improve the comparability of international postsecondary data (http://www.uis.unesco.org/Education/Pages/international-standard-classification-of-education.aspx).

System Level Data

Eurydice, which is coordinated and managed by the European Union Education, Audiovisual and Culture Executive Agency, and the OECD conduct annual and periodic surveys of information describing the structure of education systems. For example, the Eurydice report, *Key Data on Teachers and School Leaders in Europe 2013*, http://eacea.ec.europa.eu/education/eurydice/documents/key_data_series/151EN.pdf provides a range of information on national teaching practices including teacher preparation and support, professional development, and levels of autonomy and responsibilities. Other types of descriptive statistics gathered on a regular basis include instructional time for children at different age levels and teaching hours per year (see Indicators D1 and D4 in *Education at a Glance 2013*). Periodic data collections by the OECD have included such topics as teacher professional development, national assessments, and autonomy of private schools. Descriptive information provides important context for interpreting statistical data such as information on the amount of instructional time in the year can affect interpretation of teacher salaries. Also, system-level information provides important information to policy makers about how the structure of national education systems differ, such as with respect to school governance and autonomy. One of the most frequently encountered challenges in using system-level data is understanding to the degree to which federal countries may have substantively important variations in structures among the various education systems which exist within their countries.

Finance

The education finance comparisons constitute some of the indicators most closely watched by policy makers. Government finance decisions can affect the level of taxation to support government activities as well as the allocation of government funds to education as opposed to other types of government functions. Aside from government decisions, the per capita income of the country can have an important relationship with education funding. Budgetary decisions constitute one of the primary levers that policy makers have on the education system. There is a significant correlation between available national finance resources, as measured by GDP, and expenditures per student at both the primary/secondary and tertiary levels (http://nces.ed.gov/programs/coe/indicator_cmd.asp). Another type of important comparison involves the relationship of total education spending and GDP, which provides an indicator of the priority of education spending relative to other components of the economy. The finance data involve some of the more problematic statistics in international data collections. Accounting systems and principles differ quite substantially from country to country. Most of the country-reported summary data are at least partly estimated to adjust national accounting procedures to international survey definitions. While reasonable estimates can be made for many items, some types of differences are structural. For example, in the United States, the health care system is primarily based on employer/employee funding. Hence, health care costs for the teachers and other school staff are included in the education funding for the United States, while they are included in national health budgets (not education funding) for other countries with national health care systems. Despite limitations, finance data are included in most international comparisons due to the very high policy relevance.

Labor Force

Another set of closely watched data are the labor force outcomes related to education. These data include such measures as employment and unemployment rates, and median incomes, related to level of education completed. These data are collected annually for OECD countries, and there are also surveys conducted by Eurostat. The OECD measures include the labor force participation and unemployment rates, as well as the median annual income for

those who have completed various education levels. Fostering a healthy job market is a key policy arena for all countries. The educational attainment data are considered an important indicator since countries with high levels of education among their citizenry are viewed as more able to adjust to new labor skill demands and technologies. Unlike most of the education data previously described on enrollment, graduates, staff, and finance, the labor force outcomes are collected through labor force surveys based on samples in each country. In general, these labor force surveys are not centrally coordinated by international organizations as with the student assessment surveys described in the following paragraphs. The labor force surveys are nationally designed to meet national reporting requirements. However, the alignment of the definitions for such key concepts as employment, unemployment, and annual earnings are quite good. Because of the relatively strong alignment between national and international concepts for most countries, the comparability of data on labor force statistics is better than for some types of international education statistics. A key limitation is the classification of education levels as noted above on graduates, with the additional complicating factor that many countries have internal classification problems because their education systems have changed over time. Also, although nearly all the labor force data are based on statistical samples, standard errors are only available to a limited extent. While statistics based on large population groups, such as those based on 10-year age bands for ISCED Level 3 completers, are fairly robust for most countries, researchers need to be careful about comparisons involving smaller population groups. Standard error estimates currently available for selected educational attainment and labor force tables in *Education at a Glance* provide some useful guidance on the magnitude of standard errors for various types of comparisons.

Individual-Level Data Collections

Among the most important expansions of international data collections over past two decades has been the increased focus on student assessment data. In contrast to the international comparisons based on summary data reported at the national level by country statistical representatives, these achievement data have been gathered at the student level using comparable assessment survey instruments translated into national languages. The national data collections are coordinated by country representatives who manage such activities as facilitating cooperation from schools who have been selected to have their students participate in the survey. National coordinators are also involved in the design of the survey instruments to ensure that the assessment questions are in contextual and language structures that are appropriate for the students in their country. International authorities require surveys to be conducted within countries according to defined procedures. Also, the sample selections and survey administrations are monitored by international organizations to ensure high quality and consistency with established guidelines.

The international assessment data provide essential information on the ability of students to demonstrate acquired skills in key subjects, such as reading, mathematics, and science. In addition to information on average performance levels of students, the assessment data provide statistics on the range of student performance including information on low socioeconomic and migrant students, compared to other students. The extent to which countries can reduce the range of student scores can provide an indication of the success of programs to provide equity. The student-based information can also be analyzed with respect to relative variations between schools in student performance or other measures such as pupil/teacher ratios. Such information on the range in school characteristics also cannot be addressed by the summary data reported by national authorities. In addition to student assessments, two additional individual-based international education surveys have been conducted recently. A representative sample of teachers in many OECD countries has been gathered through the Teaching and Learning International Survey (TALIS). A new international comparisons milestone was reached with the release of the Programme for International Adult Competencies (PIAAC) in 2013 which provides data on adults and their performance on literacy, numeracy, and computer-related skills.

Trends in International Mathematics and Science Study

The International Association for the Evaluation of Educational Achievement (IEA) coordinates three major survey systems: The Trends in International Mathematics and Science Study (TIMSS); the Progress in International Reading Literacy Study (PIRLS); and the Civic Education Survey (CivEd). TIMSS has measured trends in mathematics and science achievement at the fourth and eighth grades on regular 4-year cycles since 1995. In addition, TIMSS Advanced, which measures trends in advanced mathematics and physics for students in their final year of secondary school, was conducted in 1995 and 2008. http://timss.bc.edu/home/pdf/TP_About.pdf. In 2011, more than 60 countries and other education systems, including the United States, participated in TIMSS. In addition to student assessment data the TMSS survey system includes surveys on student backgrounds, teachers, and schools. National research coordinators provide information on the national curriculum and education policies and practices. http://nces.ed.gov/surveys/international/intl_assessments_table.asp.

Progress in International Reading Literacy Study

The Progress in International Reading Literacy Study (PIRLS) collects information on the reading skills of fourth graders. PIRLS has been administered in 2001, 2006, and in 2011. The PIRLS assessment measures student performance on a combined reading literacy scale. There were also two subscales of purposes of reading: reading for literary experience and reading to acquire and use information and for two subscales of processes of comprehension: Retrieving and Straightforward Inferencing and Interpreting, Integrating, and Evaluation. In 2011, 53 education systems participated in PIRLS. Similar to TIMSS, additional contextual information was gathered through student background questionnaires, teacher questionnaires, school questionnaires, and in many countries, parent questionnaires.

The Programme for International Student Assessment

The OECD coordinates the Programme for International Student Assessment (PISA), which measures 15-year-old students' reading, mathematics, and science literacy. In contrast to the more curricula-based TIMSS assessment, PISA also includes measures of general or cross-curricular competencies, such as problem solving, functional skills that students have acquired as they near the end of compulsory schooling. PISA was first administered in 2000 and is conducted every 3 years. The most recent assessment was in 2012.

Teaching and Learning International Survey

The Teaching and Learning International Survey (TALIS), coordinated by OECD, is an international study of teachers, teaching, and learning environments. TALIS provides internationally comparable data on teachers and instructional practices to highlight current conditions and inform education policy. TALIS was first administered in 2008 in 24 countries. TALIS was administered again in 2013 with new survey instruments that are based on a broad international perspective on policy and research interests. Thirty-four countries and educational systems participated in TALIS 2013 which was released in June 2014.

Programme for International Adult Competencies

The Programme for International Adult Competencies (PIAAC) breaks new ground in assessing the functional literacy and numeracy skills of adults in about 25 countries in 2011–12. This complex survey, coordinated by OECD, also gathered information on the skills of adults in using computers to solve problems in a technological environment. Nationally representative samples of about 5000 adults were surveyed in each of the countries, providing information on the skill levels of adults with various education backgrounds. The background information contained information on labor force participation, occupations, educational activities, and other family and demographic background information.

Using International Data Systems

Over the past decade, there has been a large quantitative and qualitative expansion in the statistical resources available to researchers in the field of international education comparisons. There have been important upgrades to the more traditional data collections based on nationally reported summary data, including many new waves of student assessments, and completely new international data on teachers and on adult functional literacy. The ability to access data has been greatly improved, including not only high-quality publications, but new online data tools that enable researchers to produce custom tabulations and analyses. The *Resources* text box provides helpful starting points to obtain detailed descriptions about the surveys that have been cited in this article and to access data and findings that can serve as a basis for further analyses or references for public presentations.

Despite the expansions and improvements in international education data systems, data limitations remain. Although great efforts are made to adjust data for international comparability, structural differences in education practices, and curricula pose complicating factors for education authorities. Although assessments are designed to reflect curricular content that is common worldwide, there are important differences among all countries and within federal countries. Care must be used in drawing conclusions from educational systems within countries, and the extent to which those subnational units represent the rest of their country. With the array of data now available to the research community, it is possible to validate many data sources with related information from other sources. This not only serves to place conclusions on a more firm basis by aligning similar data from multiple sources, but also can bring together a more complete picture of education across the world.

Resources

The UNESCO Institute for Statistics (http://www.uis.unesco.org/Education/Pages/default.aspx) has a long tradition of collecting education data, and makes information through publications such as *Global Education Digest* (http://www.uis.unesco.org/EDUCATION/Pages/global-education-digest.aspx), and online data tools (http://stats.uis.unesco.org/unesco/TableViewer/document.aspx?ReportId=143&IF_Language=eng).

The OECD publishes the widely publicized annual report Education at a Glance (http://www.oecd.org/edu/eag2013%20(eng)–FINAL%2020%20June%202013.pdf), and supports an extensive program of shorter reports and data tools (http://www.oecd.org/edu/). OECD offers access to microdata (data sets with individual level responses for use by researchers for advanced analyses) such as PISA through data tools and downloadable data sets (http://pisa2012.acer.edu.au/).

Education data for European Union countries are compiled by a number of agencies. The statistical data are compiled primarily by Eurostat (http://epp.eurostat.ec.europa.eu/portal/page/portal/education/introduction). Eurostat prepares a variety of reports on education and their web site contains a large array of statistical tabulations. Access to individual data is provided only research organizations. Other European Union agencies such as Eurydice (http://eacea.ec.europa.eu/education/eurydice%20/index_en.php) and European Centre for the Development of Vocational Training (http://www.cedefop.europa.eu/EN/Index.aspx) provide more specialized information on European education systems.

The TIMSS and PIRLS International Study Center at Boston College provide a comprehensive range of products and documentation for these large survey systems (http://www.timss.org/). These products include methodology and findings reports, data tools, and tables. Microdata can also be downloaded from their web site for more complex analyses.

Within the United States, the National Center for Education Statistics (http://nces.ed.gov/surveys/international/) hosts some convenient summaries of international data http://nces.ed.gov/surveys/international/intl_assessments_table.asp and advanced data tools that enable access to TIMSS, PIRLS, and PISA data for the United States as well as other countries participating in the surveys (http://nces.ed.gov/surveys/international/ide/).

Data Bases and Statistical Systems: Environment and Urban Studies

Erika Nóra Regös, Max-Weber-Institute for Sociology, Heidelberg, Germany

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The article on Statistical System: Environment, Urban Studies, and Human Development will demonstrate the importance of statistics on environment, urbanization, and human development to social science. All three fields of this article provide the readers with access to the most reputed national and international databases and frameworks in these fields. Additionally it will enhance the readers' basic understanding of the structure and dynamics of today's rapidly changing global environment, and its impact on living conditions.

Introduction

Statistics on environment, urbanization, and human development are multidisciplinary, their sources are dispersed, and a variety of methods are used for their compilation. Environmental statistics generally aim to describe the quality and availability of natural resources, natural events that affect the environment, the impacts of these resources and events, as well as social responses to these impacts. Urban studies usually compile housing and real estate economies in order to measure infrastructure and quality standards of housing and the degree of urbanization of a given environment. In addition to the description of environmental quality standards, human development studies have put increasing emphasis on the measurements of basic processes and contexts of human life, such as the measurement of human well-being, life expectancy, and life satisfaction. Although from different perspective, all three fields aim to describe the quality standards of life and changes over time according to objective key figures.

Environment statistics, urban and human development studies, and related fields are usually compiled and disseminated by government departments, central statistical services, research institutes, and international organizations. They are often interrelated with statistics in other fields, for example, with data on education, health, and gross domestic product (GDP).

Statistical Systems

Environment

History

During the last four decades, various national and international efforts have been made toward developing a system or framework for environment statistics, either for a planned program of statistics or for presenting available data in a coherent statistical publication. As a conceptual framework, the United Nations Conference on the Human Environment (Stockholm, June 1972) was the first global conference to signal that environmental concerns had increasingly become the subject of mainstream socioeconomic policies. As a more empirical way, the first initiatives for the development of environment statistics at international level stemmed from two meetings of the Economic Commission for Europe (ECE) in 1973, which was followed by pioneered work on standard environment statistics classifications by the UNECE Statistics Division. Environment statistics programs also started at Organisation for Economic Co-operation and Development (OECD) and later at Eurostat, focusing on data collection and indicator development, in the late 1970s and early 1980s.

In the second world conference, the United Nations Conference on Environment and Development (Rio de Janeiro, June 1992), increasing emphasis was put on integrated environmental and economic accounting. One of the main outcomes of this conference was the adoption of Agenda 21, which sets out a series of principles and actions for achieving sustainable development (Hens, 1996).

As a result of the increasing demand for environmental information, the first global collection of environment statistics was launched by United Nations Development Group (UNSD) in 1999. Since then it has been established in a biennial basis. After 1 year, in 2000, 189 countries of the United Nations agreed on 10 globally environmental indicators set up under the Millennium Declaration (2000) by the UNSD. Those indicators are developed to monitor progress, and simultaneously committed the countries to the achievement of the eight declaration's goals and the other targets by 2015.

Most recently, a huge number of documents and programs have been emphasizing the increasing importance of environmental statistics, information, and indicators. Especially, the outcome document, 'The Future We Want' of the United Nations Conference on Sustainable Development (Rio + 20, Brazil, June 2012) highlights the necessary advancement in environmental information. It is also important to mention the European Commission's efforts to integrate seven key environmental indicators in its general framework on 'strategy for sustainable development.' The OECD regularly updates its environmental data and indicators given the need of reliable and harmonized data on environment and including the ways in which it is affected by economic activity.

The Organization of Environment Statistics

Research on environmental data varies from country to country and over time, which makes an international harmonization more difficult, although there have been some successful efforts to organize them internationally.

The Statistical Office of the United Nations Secretariat was the first to identify those common characteristics that could be incorporated into a widely applicable international framework. The results can be divided into four basic approaches: (1) the media approach, (2) the stress-response approach, (3) the accounting approach, and (4) the ecological approach.

The stress-response approach, originally developed by Statistics Canada as a "Structural Framework for the Stress-Response Environmental Statistical System," is the only approach that analyses the interactions between human activities and the environment. Its main focus lies on impacts of human intervention within the environmental (stress – such as waste generation, extraction of natural resources, and the production of hazardous substances) and the environment's subsequent transformation (environmental response). All other three approaches give information on the different environment issues without any deeper consideration of the human intervention in the environmental course: (1) the media approach deals with the major environmental components of air, water, land/soil, and the artificial environment; (2) the accounting approach analyzes the flow of these components from their extraction (harvest) from the environment, through successive stages of processing and final use, to their return to the environment; whereas (3) the ecological approach gives an overview on a variety of models, monitoring techniques, and ecological indices such as the assessment of population diversity and dynamics, of biomass production and its productivity, stability, and resilience of ecosystems.

Despite the presence of these four different basic approaches, the existing national and international approaches indicate a preference for the combination of the media and the stress-response approaches. To operationalize a set of activities that exert stress on the environment, (1) measures of stressors, (2) analysis of environmental response, (3) measurement of collective and individual responses, as well as (4) assessment of stocks of natural resources, artificial structures, and potentially hazardous substances have been developed. (See more on the stress-response at the Web site of the World Bank Group at: https://www.virtualstatisticalsystem.org/themes/theme/31-environment/?no_cache=1.)

Framework for the Development of Environment Statistics

In 1984 the Framework for the Development of Environment Statistics (FDES) was developed and published by the UNSD to systematically present and organize environmental statistics. Its first two technical reports, the 'Concepts and Methods of Environment Statistics: Human Settlements Statistics' (published in 1988) and 'Concepts and Methods of Environment Statistics: Statistics of the Natural Environment' (published in 1991) describe in detail the sets of statistical variables within the FDES.

Recently, the FDES have been updated and enlarged by two aspects: (1) 1984, the FDES has been completely revised, based on improved scientific knowledge about the environment and new statistical requirements created by emerging environmental policies and concerns; and (2) a core set of environment statistics that has been developed aiming to create an agreed, limited set of environmental statistics that are of high priority and relevance to most countries. Actually, it is Tier 1 of a greater (though not exhaustive) basic set of environment statistics composed of three ranks according to the level of relevance, availability, and methodological development of the statistics. The aim of the revision was to emphasize the relationship of human activities and natural events in more detail by creating information categories that can describe a sequence of action, impact, and reaction. According to the UNSD, the revised FDES 2013 aims to guide nation-states in the development process of their own environment statistics programs primarily at early stages. In addition, it aims to be of help for all three institutional levels (national, international, and regional) in order to organize and strengthen the production of environment statistics.

UNSD also cooperates closely with other organizations like the OECD, the Statistical Office of the European Union (Eurostat), United Nations Environment Programme (UNEP), the UN Division of Sustainable Development (DSD), and the regional commissions, as well as with specialized agencies, secretariats of international conventions, NGOs, and others in order to create synergies and to avoid duplication of efforts in data collection.

Organisation for Economic Co-Operation and Development

The OECD has been developing environmental indicators since the early 1990s and has published the first international sets of environmental indicators. These also included the OECD Core Set of Environmental Indicators. By ongoing revision and improvement of its environmental indicators, nowadays those indicators help to integrate environmental considerations into sectoral policies, such as energy, transport, and agriculture, and to measure progress in decoupling environmental pressures from economic growth. Most recently, the OECD has developed a set of indicators to monitor progress toward green growth. (See more at the OECD report 'Environment at a Glance' online at their Web site http://www.oecd-ilibrary.org/docserver/download/9713051e.pdf?expires=1395789956&id=id&accname=guest&checksum=1B9A2B7C9F583B4823DABEA16639F642.)

The Statistical Office of the European Union

Eurostat, The Statistical Office of the European Union, situated in Luxembourg, has also published a number of compendia about environmental statistics at a European level. In addition, and in response to an agreement by the European environment ministries at the Dobris Castle, a pan-European report was completed in 1995 (Dobris Assessment). Currently, the Eurostat environmental accounts include indicators on climate change and greenhouse gas emissions, waste generation and treatment, water resources, abstraction and use, wastewater treatment, forestry and biodiversity, chemicals, material flow accounts, and relevant financial indicators such as environmental protection expenditure and environmental taxes. The indicator data are collected by the Eurostat and the European Environment Agency (EEA) and are available from the EU, its member states, European Free Trade Association countries, and candidate countries. (For detailed data please check the Eurostat Web site at http://ec.europa.eu/eurostat and the data taken from the EEA at http://eea.europa.eu.)

The European Environment Agency EEA

EEA is an agency of the EU established in 1990 to provide sound and independent information on the environment. It is a major information source for those involved in developing, adopting, implementing, and evaluating environmental policy. Currently, the EEA has 33 member countries. EEA's main clients are the EU institutions and the member countries. In addition, EEA also serves other EU institutions such as the Economic and Social Committee and the Committee of the Regions.

Most recently, the implementation of an improved environmental system for Europe, the so-called 'Shared Environmental Information System (SEIS),' has become the main focus of the EEA 2009–2013 Strategy and its daily operations. Originally, it was a proposal of the European Commission (EC) entitled 'Toward a Shared Environmental Information System (SEIS)' in 2008. Since that time, SEIS has become a collaborative initiative of the EC and the EEA and its Eionet (European environment information and observation network), consisting of 38 countries. The SEIS's goal is to create an improved environmental information system for Europe based on a network of public information providers that share their environmental data and information. (For more information on EEA Web site at: http://www.eea.europa.eu.)

The United Nations Environment Programme

The UNEP, founded as a result of the United Nations Conference on the Human Environment in 1972, is an agency of the United Nations that coordinates its environmental activities, i.e., assisting developing countries in implementing environmentally sound policies and practices. The so-called Environmental Data Explorer is the authoritative source for data sets used by UNEP and its partners in the Global Environment Outlook (GEO) report and for other integrated environment assessments. Its online database holds more than 500 different variables, such as national, subregional, regional, and global statistics or geospatial data sets (maps), covering a wide range of topics such as freshwater, population, forests, emissions, climate, disasters, health, and GDP. (See more at their Web site at http://www.unep.org.)

The UN Division for Sustainable Development

The DSD provides leadership in promoting and coordinating the implementation for a sustainable development agenda of the United Nations. The division puts their main focus on five core functions: (1) support to UN intergovernmental processes on sustainable development, (2) analysis and policy development, (3) capacity development at the country level, (4) interagency coordination, and (5) knowledge management, communication, and outreach. Even though there is no special database on environmental indicators provided by the division, its contribution to the sustainable development is highly valuable. By participating in programs such as the Expert Group Meeting on 'Institutionalizing sustainable development indicators for measuring progress of national strategies' in Barbados in 2009, it encourages national governments and a range of regional institutes to conceptualize and implement their own systems of indicators on sustainable development. (See more on the Expert Group Meeting online at: http://sustainabledevelopment.un.org/content/documents/1380REPORT_final.pdf.)

United States Environmental Protection Agency

In 1970 the United States Environmental Protection Agency (EPA) was established to consolidate the variety of federal research, monitoring, standard-setting, and enforcement activities into one agency to ensure environmental protection for the United States. With help from numerous partners, EPA has compiled a set of databases tracking down the following science topics: air, climate change, health risks, pollutants and contaminants, waste, and water. Most of these indicators focus on the United States, but some include global trends to provide a context or a basis for comparison. As EPA points out, their indicators represent a selected set of key measures for the respective scientific area, and do not reflect an exhaustive group of all possible indicators. Moreover, all indicators are based on peer-reviewed data from various government agencies, academic institutions, and other organizations. The selection of these indicators is based on the quality of the data and other criteria.

Additionally, EPA has also developed a data finder to point out data sources that EPA manages and to facilitate access to environmental information (it can be found at: http://www.epa.gov/datafinder/). Similarly, the federal site, Data.gov, helps people to find, download, and use data sets that are generated and conducted by the federal government. (See more details on the EPA's indicators, tools and methodologies here: http://www2.epa.gov/science-and-technology and on the Federal government Web site at: http://www.data.gov/.)

Human Development

Most of the indicators on environmental statistics show changes are occurring throughout the Earth's climate system, including increases in air and ocean temperatures, rising extreme weather events, a rise in sea level, widespread melting of glaciers, and longer ice-free periods on lakes and rivers. Such changes can represent a wide range of challenges to human well-being, the economy, and natural ecosystems. For that and other reasons, many researchers have turned their attention to construct indicators, which study human development best.

Human Development Index

The core insight at the center of the human development approach remains constant and as valid today as two decades ago: "Development is ultimately best measured by its impact on individual lives" (UNDP, 2014: 7).

The Human Development Index (HDI) was developed by the UNDP to rank developed, developing, and underdeveloped countries by their level of human development. It measures the average achievements in a country according to three basic dimensions of human development: (1) a long and healthy life (life expectancy), (2) access to knowledge (mean and expected years of schooling), and (3) a decent standard of living (GINI per capita) (UNDP, 2014: 2). The HDI was created to emphasize that people and their capabilities should be the ultimate criteria for assessing the development of a country, not economic growth on its own. Additionally, the HDI is often used to question national policy choices. (For a full elaboration

of the method and its rationale, see Klugman et al. (2011), for more information on the general use and indicators of the HDI see the following Web site: http://hdr.undp.org/sites/default/files/hdr_2013_en_technotes.pdf.)

Inequality-Adjusted Human Development Index

The Inequality-adjusted Human Development Index (IHDI) was introduced by UNDP in their Human Development Report 2010. It was created to measure the level of human development of people in a society that accounts for inequality. Under perfect equality the IHDI is equal to the HDI. However it falls below the HDI when inequality rises. In other words, the IHDI can be seen as the actual level of human development (taking into account inequality), while the HDI can be viewed as an index of the potential human development that could be achieved if there is no inequality. The index has been applied to 132 countries so far. (For more information and data available see their Web site at: http://hdr.undp.org/en/statistics/ihdi.)

World Population Prospects

The World Population Prospects represents the official United Nations population estimates and projections conducted by the Population Division of the United Nations Department of Economic and Social Affairs of the United Nations Secretariat. It is used widely throughout the United Nations and by many international organizations, research centers, and academic researchers. The 2012 revision of the world population prospects represents the 23rd round to display key demographic indicators for each development country and area within 1950–2100. (Detailed information about indicators on demographic variables such as population, mortality, fertility rates, on data sources used to derive estimates for those indicators, and on method used to derive mortality estimates, age mortality pattern, and child mortality can be found at their Web site at: http://esa.un.org/unpd/wpp/unpp/panel_indicators.htm.)

Housing and Urban Studies

Cities are seen as both the source and solution of today's economic, environmental, and social challenges. For instance, they are home to 75% of the EU's population, they account for about 80% of energy use, and they generate about 85% of Europe's GDP (European Commission, 2013). Therefore, cities are central to achieve sustainable and inclusive growth within an increasingly competitive global context. That is the reason why urban development – economic, social, and environmental – is central to several international frameworks, such as to the Europe 2020.

History

To develop indicators on health of housing, real estate markets, and on cities and their inhabitants, much effort has been undertaken over the past 40 years (Muth, 1969; Mills, 1972; Hochwald, 1961; Tiebout, 1962). Hirsch's (1966), Flax's (1978), and Murphy's (1980) are just a few of early works in urban economics focused on data and indicator issues. The popularity of *Money* magazine's annual rating of cities as well as Savageau and Boyer's annual almanac urban indicators have even become popular (Malpezzi and Mayo, 1997: 3). With the early 1990s, there was hardly any consistent data available for international comparisons of urban development outcomes, with an exception of some urban population figures (see World Bank, 1994). Since the early 1990s, some research on international indicators has started to fill this gap by an awakening interest in comparing housing and urban development indicators across countries. Especially, the United Nations and the World Bank sponsored the collection of several dozen basic urban indicators by individual researchers in a sample of 51 countries. The aim was to document and explain ideal collection procedures and to maximize comparability. The collected indicators could then be used in both a diagnostic and in a comparative way (for example see Mayo, 1993) or for the construction of indexes for housing policies and subpolicy such as regulation and taxation (Angel and Mayo, 1996). These initial efforts of the United Nations and the World Bank toward international comparability resulted in an expansion, both in terms of more countries and a wider range of indicators. In addition to housing and real estate indicators, a huge number of indicators related to socioeconomic development, infrastructure, transport, the urban environment, and local governments have been collected at the turn of the millennium. In the United States, the Department of Housing and Urban Development has taken the lead in preparing an initial set of indicators on 100 large U.S. metropolitan statistical areas (Glickman et al., 1996). In Europe, the Eurostat 'Urban Audit' data collection has been providing information and comparable measurements on the different aspects of urban life quality in the European cities since 2003.

This brief historical paragraph on housing and urban studies relies mostly on the work of Malpezzi and Mayo (1997). In addition to the data bases presented and works cited therein, representative examples include, among many others, the work of Case and Schiller (1989) and Thibodeau (1995) on housing prices; of Holtz-Eakin and Rosen (1989) and Aschauer (1989) on infrastructure; of Ladd and Yinger (1989) on fiscal and governance measures; and of Rose (1989) and Malpezzi (1996) on urban regulations.

Housing and Urban Development

The United States Department of Housing and Urban Development (HUD) is a cabinet department in the executive branch of the United States. Founded in 1965 and assigned to the United States Secretary of Housing and Urban Development, the HUD was created to develop and execute policies on housing and metropolises.

According to the HUD's own mission statement, it aims to create strong, sustainable, inclusive communities and quality affordable homes for all persons within the United States. The HUD is working to strengthen the housing market, to bolster the economy and to protect consumers; to meet the need for quality affordable rental homes; to utilize housing as a platform for improving quality of life; to build inclusive and sustainable communities free from discrimination; and transform the way HUD does business (HUD, 2013: 2).

More recently, several subprograms have been established, such as the 'HUD youthbuild programs' providing "disadvantaged youth with opportunities for employment, education, leadership development, and training in the construction or rehabilitation of housing for homeless

individuals and members of low- and very low-income families." (For more information: http://definitions.uslegal.com/h/hud-youthbuild-programs-hud/.)

The United Nations Centre for Human Settlements (UN-HABITAT)

The United Nations Human Settlements Programme, UN-HABITAT has been a pioneer organization in the collection of urban indicators. In 1978 UN-HABITAT was established through a resolution of the UN General Assembly to promote socially and environmentally sustainable towns and cities with the overall goal of providing adequate shelter for all. In 1991, UN-HABITAT initiated the Housing Indicators Programme, focusing on monitoring the quality of shelters. In 1993 the program was re-developed and became the Urban Indicators Programme, which focuses on a larger range of urban issues. In 1996 and 2001, the Urban Indicators Programme produced the first two global urban indicators databases the Global Urban Indicators Database Version 1 (GUID1) and the Global Urban Indicators Database version 2 (GUID2), presented at the HABITAT II conference and the Istanbul+5. The aim was to establish regional trends in key urban issues in a global perspective. In 2005, the Monitoring Urban Inequities Programme produced the Global Urban Indicators Database (III). In addition to addressing the HABITAT Agenda, this database provided information on the Millennium Development Goals, particularly for the target on achieving a significant improvement in the lives of at least 100 million slum dwellers. Since 2006, the Global Urban Indicators Database has been updated annually. (For the list of UN-HABITAT indicators see: http://ww2.unhabitat.org/programmes/guo/documents/urban_indicators_guidelines.pdf.)

The UN-HABITAT Monitoring System

The UN-Habitat monitoring system was established by UN-HABITAT in response to a decision of the United Nations Commission on Human Settlements. It called for a mechanism to monitor the global progress in implementing the HABITAT Agenda and to monitor and evaluate global urban conditions and trends at the international, regional, national, and local level. This monitoring function is provided through two main instruments: Global Urban Observatory (GUO) and Best Practices and Local Leadership programme (BLP). The GUO has the task to monitor and evaluate the global urban conditions and trends. It includes urban indicators, statistics, and city profiles. The BLP was established to make use of information and networks in support of the HABITAT Agenda Implementation. Both programmes operate under the Monitoring Systems Branch, which has the overall mandate to monitor the progress of the HABITAT Agenda and the Millennium Development Goals. (For more information see the UN monitoring system online at: http://ww2.unhabitat.org/programmes/guo/.)

Eurostat – Urban Audit

The Urban Audit is a statistical data collection by Eurostat providing statistical data and information on living conditions in Europe. After a 'pilot'-audit in 1999, the first full-scale European 'Urban Audit' for the then 15 countries of the European Union took place in 2003. In 2004, the project was extended to the 10 new Member States plus Bulgaria, Romania, and Turkey. For the 2003/2004 data collection exercise 336 variables were brought together, covering most aspects of urban life. The second full-scale data collection for the Urban Audit covered the time period between 2006 and 2007. It involved 321 European cities in the then 27 countries of the European Union along with 36 additional cities in Norway, Switzerland, and Turkey. The basic philosophy was to deviate as little as possible from the concepts used in the 2003/2004 collection. However, some changes were made with the aim to improve comparability, data availability, and quality (Eurostat, 2014). According to the 'EU – Cohesion Policy 2007–2013,' the newest data collection includes 357 European cities providing data with over 330 indicators for the quality of urban life in Europe cities on demography, housing, health, crime, the labor market, economic activity, income disparity, local administration, civic involvement, educational qualifications, cultural infrastructure, and tourism (European Commission, 2013: 1). Data collection has been assembled every 3 years. However according to the Eurostat Web site an annual data collection is being planned for a smaller number of targeted variables. (For more information the indicators and database: http://epp.eurostat.ec.europa.eu/portal/page/portal/region_cities/city_urban/.)

In addition to the GEO and the Urban Audit databases, there are many other databases on indicators related to housing and land in an international basis, such as the World Bank Data & Statistics, UNECE Environment and Human Settlements Division, the World Gazetteer, and the European Mortgage Federation.

The Future of Empirical Data on Environment, Human Development, and Urban Studies

A main task of the environmental and urban statistics work today is the harmonization and standardization of the definitions and classifications of indicators at the international level. Improved tests and amended theory at an international basis are critical to an enhanced understanding of the state of environment, urban markets, and human well-being. A 'standard' list of global indicators can not only help to monitor current global states and trends of living conditions, but it can also represent the impetus for a better understanding of divergences and communalities between regions, countries, and their citizen.

Currently, major international research effort was undertaken in most of the countries with support from numerous academics and other researchers, from the United Nations, the World Bank, the European Commission as well as number of national governments. In the light of these past developments, international data collection, collation, analysis and reporting could help us to monitor past and current trends of environmental and urban indicators and to forecast their possible development in the near future. Continued serious and globally concerted work on environmental, urban, and human developmental indicators will improve and illuminate public policy. Additionally it will enhance our basic understanding of the structure and dynamics of today's rapidly changing global environment, and its impact on living conditions.

Abstract

Health information systems represent a complex series of efforts to collect, analyze, and report information systematically and sustainably and to derive knowledge and evidence serving various purposes with the ultimate aim of improving health. The terminology used in relation to health information lists notions such as *health data, health information or health statistics,* and *knowledge or evidence*. The history of health statistics offers a picture of how the diversity of data has increased over time and how better health information has allowed scientists and health practitioners to reach better health outcomes. *Providing an evidence base* for overall policy and resource allocation, *ensuring access* (especially for vulnerable groups), *monitoring the quality of care* provided by the health system, *understanding overall public health* and the factors affecting it in different settings and *ensuring transparency and accountability* are the main purposes of health information systems. Examining the interactions between data used in national and international contexts is important in view of gaining better efficiency of health interventions. Considering the social determinants of health and their intersectoral nature prompts the need to gather data generated in other areas and sectors other than health. *Registration systems* such as civil registration and vital statistics are an important source of health information. Depending on the context, resources such as *registries, notification systems, health surveys, nonhealth sector sources* are also employed to obtain health statistics. Data integration is instrumental in monitoring health policy, monitoring and understanding of diseases, and better tracking individual health and well-being. However, ethical considerations and policy precautions are vital in data collection, storage, use and destruction, security and consent.

Introduction

Health information systems comprise the actions taken to collect, analyze, and report information systematically and sustainably and to derive knowledge and evidence in the field of health. This requires a dedicated infrastructure, including human resources, technology, software and databases. Many health information systems were born out of long-standing traditions, particularly in industrialized countries. These historic traditions have led to infrastructures and content which is very contextual and often nationally specific resulting in sometimes poorly comparable information elements at the international level. The national focus of health data can also make it difficult to analyze global crossborder flows. The greatest challenge remains the lack of good information systems in many developing countries.

This article will address these issues and aims to define the various aspects, content, and collection systems as well as purposes for health information. The national and the international challenges can no longer be separated in a globalized world, in particular, this relates to issues of ownership, commercialization, and governance of data, as well as the potential of the data revolution for the twenty-first century. Health statistics have gained significant political and commercial relevance.

Health statistics have been used in some form or another to assist with public health practice for hundreds of years, yet no universally agreed definition exists to date. While there have been numerous attempts to do so, the terms 'health statistics,' 'health data,' 'health information,' even 'informatics' are often used interchangeably. To complicate matters, what is collected and reported is information about deaths, diseases, and disabilities rather than information on health, well-being, and their determinants. Only recently have there been increasing attempts to provide measures of well-being by looking at people's material living conditions and quality of life across the population (OECD, 2013).

Terminology (What Are Health Statistics?)

In the context of its European Health Policy *Health 2020*, the WHO Regional Office for Europe (2013a) has recently made an attempt to clarify the definitions used for health information through a support tool for its Member States (WHO Regional Office for Europe, 2013b). The definitions proposed interpret health statistics in the widest sense as the content of health information systems:

- Health *data* (quantitative and qualitative) are the basic units of what is collected, for example, the raw numbers in birth and death registers, on the registrations of births or deaths; raw numbers on volume of medical care provided, numbers on medical care for provided in relation to a specific disease; or the results of a legislative measure banning smoking in public places.
- Health *information* or health *statistics* can be seen as organized data, that is, data that have been processed or arranged in such a way as to provide a clear picture of a situation in a particular place. For example, indicators based on data from various registers that have been collated and checked for omissions or duplications in order to produce complete information on births and deaths; analysis of data from a variety of sources in order to compile complete information about registration; comparisons of long-term trends or between geographic areas; analysis of primary care records to provide a picture of health workers' compliance with guidelines for medical care in relation to specific diseases.
- *Knowledge (or evidence)* can be seen as information in context, that is, information combined with understanding, values,

and a wider, longer-term approach to provide 'actionable information.' For example, an analysis that combines information from various sources on outcomes and their causes used to form the basis of action to reduce premature mortality; the results of an evaluation of a particular medical device that enables an analysis of its cost-effectiveness as the basis for a recommendation on its wider use; an analysis of the impact of implementing specific aspects of antismoking legislation as the basis for a recommendation on their inclusion in national legislation.

Historical Origins of Health Statistics

The historical origins of health statistics are closely related to the development of the modern nation-state and the increased political interest in systematically assessing the vital statistics related to the population (Porter, 1999). For the purpose of this article, four defining phases in the development of health statistics are identified:

Vital Statistics

It is often underestimated how much the history of public health is also the history of vital registration and statistics. The beginnings of death registration can be found in the mid-fifteenth century Italian city-states, in most developed countries they have been gathered for at least a century. A shift occurred when new methods and systems of information gathering were developed in the seventeenth century to better understand the interface of the wealth and health of nations. The groundbreaking work of John Graunt (1620–74) for example, included not only population estimates and (a historic first) a life table which calculated probabilities for survival, but also a proposal to create an early warning system for the onset and spread of bubonic plague in London. Fighting contagion and epidemics became one of the major tasks of states, leading to the establishment of boards of health and strict systems of medical policy, and laying the ground for what was to become one of the fundamental political debates in public health: the balance between individual rights and the demands of society (Baldwin, 2005).

Linking Health and Social Statistics

In the nineteenth century, the industrial revolution led to the deterioration of social and living conditions for large sectors of the population and the improvement of health became an integral part of a new social reform agenda. Enlightenment philosophers had considered health a human right and advocated social reform as a precondition for better health – this argument was increasingly underscored by data. For example the work of Louis René Villermé (1782–1863) and Rudolf Virchow (1821–1902) proved the association between poverty and mortality and Friedrich Engels (1820–95) showed that death rates for workers in large industrial cities were up to four times higher than in the countryside. Precise health statistics became an important political tool for reformers to argue their case in order to quantify the value of investments in better living conditions or investments in public health infrastructure and programs. Here too lie the origins of another long-standing public health debate between the moral value of health and the value of public health investments in cost–benefit terms. In setting policy priorities, health information systems became a governance tool for the state far beyond the initial focus on the control of contagion and disorder.

Sharing and Classifying Health Statistics

In the beginning of the nineteenth century it became critical to share information on disease and outbreaks. This need to collaborate – together with new international sanitary regulations – became a focus of the work of the International Sanitary Conferences as of 1851. At the national level in 1839, William Farr had already called attention to the importance of a uniform statistical classification of causes of death and he proposed a first disease classification for statistical purposes to enable precision in reporting. This was taken up by a proposal at the First International Statistical Congress at Brussels in 1853 to embark on the international statistical comparison of 'Causes of Death.' After extensive work and debate the International Statistical Institute adopted a report in 1893 which became the origin of the International List of Causes of Death, which since then has been regularly reworked and expanded and is now known as the International Classification of Diseases (ICD). In the 1920s, cooperation was developed with the Health Organization of the League of Nations, which had also taken an active interest in vital statistics, today this is one of the constitutional functions of the World Health Organization (WHO) in close cooperation with national statistical offices. The sharing of data – particularly when reporting outbreaks – continues to be a political challenge for global health.

Moving from Mortality to Disease Burden

Today's health information challenges are of a significantly more complex nature: as societies invest in the health of their population they need to have information "that is comparable, reliable and comprehensive across a wide range of conditions and exposures that cause death or ill-health in a population" (Lopez, 2005). In particular, moving beyond mortality and knowing the disease burden of mental health and chronic diseases such as depression or musculoskeletal conditions is critical for decision-makers. The *Global Burden of Disease* (GBD) Study was commissioned by the World Bank in the early 1990s and constituted a breakthrough in the international comparison of health data by using Disability-Adjusted Life Years(-DALYs), an approach which will be discussed further below. Health data have gained increasing political relevance, driving investment decisions, and access to development aid. They have also gained in commercial relevance for a global health industry and insurance industry.

Dimensions of Health Information Systems (for Whom and What Purpose?)

Different uses of health information systems require different kinds and content of information, and produced according to

different timescales and communicated in different ways. For effective learning, feedback needs to be rapid and relevant. For effective policy-making, data should provide feedback on a timescale that is relevant for decision-makers – which for most political systems is linked to election cycles. Health information about population health has different timetables, with slower-moving trends and a more complex process to collect and put together an overall picture. It serves a wide variety of purposes nationally and internationally and for many different stakeholders. Increasingly it brings together data from many different sectors.

Purpose of Health Information Systems

Health information systems serve the following purposes:

- Provide an *evidence base* for overall policy and resource allocation, with key users of such information being health ministries, finance ministries, social affairs ministries, and other parts of the government administration. For information to be used as *evidence base* it needs to be recent; showing comparative information in order to identify potential for improvement; and perhaps linking different data sources such as combining health data with cost or performance-related data in order to assess efficiency and effectiveness; in global health this can be illustrated by the introduction of results-based financing by the World Bank and the Global Fund for AIDS, Tuberculosis, and Malaria. This shift in approaches to aid, by providing funding *after* preagreed results have been achieved puts a high premium on the independent verification of results which requires high quality of data and robust measurement.
- *Ensuring access*, in particular for vulnerable groups, with users both at the overall system level and at the level of those working with the groups concerned. This kind of information has its own challenges, such as collecting data from different types of providers (e.g., special services for impoverished populations), as well as beyond the health system itself precisely in order to identify people falling outside it; this is a major data challenge in the developing world and new approaches to m-health (mobile phone technology used for health reporting in the field) are trying to address this issue.
- *Monitoring the quality of care* provided by the health system in order to ensure high standards of quality and safety, and be aimed at individual providers as well as overall monitoring agencies. This may involve a close link to professional monitoring processes such as audit and continuing professional development, and require fine-grained data down to the level of individual practitioners. Tracking quality of care may also require integrating data about a single patient across different episodes of care and different providers.
- *Understanding overall public health* and the factors affecting it in specific countries and their regions and for particular issues. This requires sources of data on key determinants, such as tobacco use, alcohol, diet, physical activity, social support, income, and employment. A wide range of sources of data from across government is required to gain a full picture.
- *Ensuring transparency and accountability*; this is often cited as a key role of health information, but is used in different senses, such as referring to access to records and information about their care for individual patients; benchmarking of health care providers; or overall transparency about the resources allocated to health systems and how they are spent to support political accountability.

Use at International Level

Health information is used not only at a national level, but is increasingly used to enable international comparisons on progress, set international priorities, provide accountability in relation to international commitments such as the Millennium Development Goals, and fulfill regular reporting requirements to international bodies such as the WHO or to donor agencies. Therefore, there is a myriad of stakeholders who make use of health statistics, most notably: international organizations, intergovernmental bodies at the regional level, development agencies, donors, policy-makers, supervisory and control bodies, the private sector, researchers, health professionals, professionals in other sectors, civil society groups, the media, the public, including subgroups of the population. Each user group will require information in all its forms – data, analytical information, and evidence-based knowledge – in order to play their part in improving health.

Information Generated in Other Areas and Sectors

The bulk of health information is collected within countries primarily for internal use. As such, it is for countries to consider what best meets their needs. The Health Metrics Network Framework (2014) and standards for country health information systems provide guidance on key elements of information systems to put in place, as well as principles for how to go about doing so. It is increasingly accepted that national health information systems should be built not only on demographic characteristics and on information generated within the health system, but also information generated in other areas and sectors. Some key intersectoral issues have been identified through other international work, notably the Commission on Social Determinants of Health (2008), and their report includes recommendations on generating relevant data and information. This has recently been more closely defined for the European Region through the Social Determinants Review for Europe (UCL Institute of Health Equity and Marmot, 2013). The wider environment is also relevant to health, and climate change in particular may bring changes that affect health; health information systems will need to take this into account, such as through including monitoring of changing patterns of threats or warning systems for extreme events.

Comparability at International Level

In order to ensure that information systems can support comparability at international level, however, it would be useful to identify areas of shared interest for international comparison across countries. Agreement on such areas will enable information systems to converge and provide

Table 1 Potential areas of interest for international comparisons

Population health and well-being
● Life expectancy and healthy life years
● Mortality by age group and condition
● Morbidity
● Avoidable/premature mortality
● Population risk factors (including inequalities)
● Subjective and objective well-being
Equity
● Distribution of health status by population/demographic/social groups
● Distribution of access/utilization of health services
● Progressivity of financing system
Health service outcomes
● Performance and quality of different elements (preventative care, primary care, secondary care, long-term care, mental health)
● Health system outcomes
● Health system processes
● Responsiveness
● Financial protection
● Efficiency

comparable information in support of improvement and mutual learning between countries. There are many potential frameworks for such international comparison. A recent review and synthesis of work in this area (Papanicolas and Smith, 2012) has identified a range of dimensions for health and health systems and potential areas of shared interest for comparison, and potential areas of interest for international comparison based on this framework are set out in **Table 1**. This analysis also includes discussion of the main possible indicators for each of these areas, together with their potential uses and limitations.

What Kind of Information?

Countries' health information comes from a huge variety of sources and covers different types of information. Health statistics are often derived from institutionalized *registration systems*, particularly in industrialized countries. This includes *civil registration* (births, marriages, divorces, and deaths) and *vital statistics* (causes of death); all countries should aim to have such registration systems covering the entire population. Ideally, vital statistics registration should operate using the ICD 10th version to permit relevant analyses and international comparisons. In addition, civil registration is key to a person's identity and nationality, human rights, and ability to access benefits. Such registration systems should be fully electronic and integrated and form the absolute basis of a country's health information reporting. Around 80 countries still do not have functioning civil registration systems; most uncounted births and deaths occur in sub-Saharan Africa and Southeast Asia. As a result, the WHO and the Health Metrics Network (HMN) have initiated an action plan 'to make every life count.'

Many countries operate special *registries* including those for cancer, immunizations, communicable diseases (such as tuberculosis), birth defects, disabilities, treatment, and exposure registries (radiotherapy, occupational hazards, etc.) which supplement mortality records with morbidity and disability information. While mortality information tends to be the most reliable where a sustainable system has been established, registries often suffer from underreporting and data quality issues; in addition, registries and vital statistics systems are not always integrated well, making the linkage of information between these systems difficult.

Notification systems are used in many countries for the surveillance of 'notifiable' diseases, most often communicable diseases but also chemical and physical hazards. Such systems are not intended to describe burden of disease but are mostly used for prevention and control, i.e., to identify potential increases in incidence and outbreaks and assist with the control of such events. Notification systems capture only a proportion of cases (often in a delayed manner) and differences in disease definitions used make comparisons over time and space difficult. The responsibilities that come with the adoption of the International Health Regulations require rapid implementation.

In many countries, *health surveys* are a source of health information particularly for nonfatal health outcomes. Such surveys are often population-based, that is, cover a representative portion of the entire population. They may include information and/or measurements of health status and health determinants, and information on access to and use of health services, as well as health service costs. Surveys can also obtain information from private health care providers that are often not available to public sources. Some countries run regular surveys (including the European Union Member States), those that operate the Demographic and Health Surveys and the Multiple Cluster Index Surveys, to name but a few. These surveys are of huge value but should not replace the establishment of civil registration and vital statistics systems in countries.

Information relevant to health may also be obtained from *nonhealth sector sources*. In many countries, the civil registration data are under the governance of ministries of the interior or justice and therefore already outside the health sector. Social services may provide information on social determinants of health (including social support, welfare, child protection), the employment sector information on unemployment rates, the public safety sector on road traffic accidents and violence, the justice system on crime rates, the education sector on school enrollment, education achievement, etc. Such data are becoming increasingly relevant where countries adopt a whole-of-government approach to public health; unfortunately, these information systems are rarely integrated and data linkage is the exception. Accessing and analyzing such information is therefore time consuming and challenging.

Data integration is a key component for the understanding of population health and for successful monitoring of health policy. Individual data and record linkage are practiced in a number of Northern European countries where every individual is given a single identifier at birth which is used in all national information systems throughout this person's life (and beyond). This enables a unique way of monitoring a person's well-being during the life course and longitudinal follow-up in the population. Such linkage does, however, increase the sensitivity of these data and privacy protocols must be adequate to ensure that no misuse occurs.

Institutions Providing Health Statistics

Many public and private players have emerged in recent years to supply health statistics, particularly at the international and regional level. Traditional institutions include large international organizations such as the United Nations, the WHO, UNICEF, the World Bank, the EU, and the European Commission and the Organisation for Economic Cooperation and Development (OECD). These institutions try to act as knowledge brokers and support countries across the three phases of collection, analysis, and use of health information, as well as bring countries together.

Collection

Although the primary focus for collection is by its nature within countries, the WHO supports countries by providing technical expertise and acting as a focal point for sharing technical expertise between countries, including knowledge, good practice, and strategies for eHealth. "eHealth is the use of information and communication technologies (ICT) for health. WHO works with partners at the global, regional and country level to promote and strengthen the use of information and communication technologies in health development, from applications in the field to global governance" (WHO – eHealth, 2014).

At global level, WHO plays a vital technical role in establishing and maintaining international classifications, most notably the ICD (WHO Family of International Classifications, 2014). These classifications provide essential support for the collection of health information within countries, as well as for its comparable analysis at the international level. The WHO Regional Office for Europe also maintains a range of databases, in particular the European Health for All Database as well as others on more specific topics (WHO Regional Office for Europe – Data and evidence – Databases, 2014).

Analysis and Interpretation

The World Health Reports and the European Health Reports, as well as other annual statistical publications of the WHO provide key mechanisms for analysis and interpretation of health information, in particular comparative analysis across the globe and regions. The databases provided its electronic health information portal also constitute a core resource enabling comparative analysis by countries and third parties, and are an international reference point for comparative analysis in health.

Ensuring Evidence-Informed Policy-Making

The WHO can also support the process of bringing knowledge and evidence into policy. WHO policies and publications are key to the dissemination of health information and play a vital role in crystallizing analysis and emerging consensus on health issues. The WHO can provide an authoritative external voice in support of evidence-informed policy discussions within countries. Structures such as the Health Evidence Network (WHO Regional Office for Europe – Health Evidence Network, 2014) and the Evidence-Informed Policy Network (WHO Regional Office for Europe – Evidence-informed Policy Network, 2014) bring capacity building and tools for knowledge translation directly to countries.

The European Commission and OECD are major producers and users of health statistics. While all Directorate-Generals of the European Commission are involved in data collection and analysis, the main thrust rests with Eurostat and the Directorate General for Health and Consumer Protection. This includes regular European Union wide surveys such as European Health Information Surveys, European Health Examination Surveys, and surveys conducted by Eurostat, such as the European Surveys on Income and Living Conditions. The OECD may collect its own data, or use data from WHO Europe, to produce the Health at Glance series. The latter is done to a large extent with WHO and Eurostat through the joint data collections on nonmonetary health outcomes.

What Is Required for Countries to Have Functioning Health Information Systems?

Institutional

An essential requirement is some form of national infrastructure with the capacity to oversee and coordinate a health information strategy to systematize and integrate the information; the independence is to ensure that the information and analyses are accepted as credible and authoritative; and the capacity to ensure that the necessary expertise and skills can be developed and retained. The structure might take the form of a national agency or institute, or the task might be entrusted to an academic institution or partnership of various institutions. Whatever the form, some central, independent, sustainable structure for health information is essential for the long-term success of a health information strategy; it must ensure the adherence to international agreements on data provision.

Legal

The collection of information about health is sensitive and is rightly subject to legal protection. On the one hand, the privacy of personal information must be safeguarded; on the other hand, there is a clear public interest in collecting and disseminating information that can help to improve health now and in the future. Many countries and the European Union have specific legislation on this issue, which ensures sustainability, harmonization, and compliance.

Many countries have a well-established legal framework that balances these different objectives. Changes in data processing brought about by modern information and communication technology, however, have led many countries to review their frameworks to ensure that they are adapted to current circumstances. There is a risk that, in seeking to protect individuals against unduly use of their personal data online, well-founded health information systems could be restricted if the consequences of potential misuse of data are not fully understood. It is essential that countries ensure that their legal frameworks for data collection and processing strike the right balance, allowing health information to be collected, analyzed, and communicated while protecting the privacy and confidentiality of individuals. This is pertinent to many aspects of

data collection (for example, access to patient data), information sharing, (for example, tracking who has access to what data and information, ensuring secure access and transmission) and policy (for example, ensuring that any publicly available information is anonymous).

Health professionals also need protection in the use of data. Monitoring systems for quality and safety rely on accurate, honest reporting of data by professionals, but this may be compromised if honest reporting by well-intentioned professionals could result in punitive sanctions. Here again, an appropriate balance must be found in each country to facilitate open, accurate reporting while ensuring that appropriate corrective action is taken when necessary. These types of data are especially critical for comparative international work on effectiveness and efficiency of health systems.

Technical

Data Collection Systems

The HMN describes the principal sources of health data that should constitute the core of national health information structures. Other less typical sources could also be considered, such as data from other government sectors (for example, social security benefit entitlements, justice system records) or from nongovernment actors, such as purchasing patterns (for example, alcohol sales). Health information strategies should include consideration of what data and information are essential and how to ensure their availability. At the European level, the aim should be to identify a minimum data set for core health information and a set of harmonized indicators to ensure comparability at the regional level.

Analytical Capacity

Additional work is required to turn data into meaningful information and knowledge. An essential part of a health information system is therefore the recruitment, retention, and training of skilled analysts who can do such work consistently over the long periods of time required to analyze health data series, for example. This requires a stable structure for health information. Analysis also depends on continual contact with the wider community of analysts, in particular in the academic world, in a multidisciplinary approach. Making health data available to external analysts (with appropriate safeguards to ensure data protection) can help to ensure up-to-date, independent analysis. International collaboration and comparative analyses can bring valuable additional perspectives and ensure that the analyses reflect international best practice.

Information Technology

One of the major changes in recent years has been the use of information and communication technology to collect, process, and communicate information in new ways. Ensuring that health information systems make good use of this technology is an essential component of health information strategies and their development. An example of using technology in health is the increasing availability of electronic medical records. Such technology may also reduce the administrative burden of health information systems. Interoperability is a central goal within and between systems, to ensure the generation of accurate data and to support good provision of health care.

The omnipresence of technologies such as mobile phones may also allow for the collection and provision of health information in new ways. Realizing the potential of information technology for health information will require that appropriate mechanisms be built in to systems during their development, which will require the active involvement of people responsible for health information systems in wider eHealth initiatives. This has shown particular innovative potential in developing countries.

Resources

Health information systems represent extremely good value for money and health information strategies should acknowledge this. These systems provide the information essential to manage systems, ensure that health system resources are used efficiently and effectively and improve health overall. For a tiny fraction of their total cost; for example, the proportion of national spending on cancer registries in Finland in 2007 was only 0.0037% of total spending on cancer (Commission of the European Communities, 2009). Moreover, health information systems are a prerequisite for good governance, accountability, and transparency. Yet, it can still be difficult to secure the necessary resources for health information strategies and systems particularly in developing countries. The investment is inherently long term when compared with immediate needs for clinical services, for example. Nevertheless, investment in health information is vital if the much larger resources for health care are to be used effectively.

The Dynamics between National and Global Health Actors in Collecting and Sharing of Health Data

Data are playing an ever larger role in global health – some speak of a data revolution. Yet challenges to the comparability of data, the quality of data, and the reliability of data when countries or agencies wish to propose policies based on such reporting still need to be addressed. When the political stakes are high, for example, in reporting on the Millennium Development Goals by country, differences in estimations between various agencies exist and are extremely confusing for users and policy-makers. The WHO, World Bank, UNICEF, and the UN Statistics Division have therefore joined forces and established an Interagency Group on Mortality Estimates to produce joint estimates for infant, child, and maternal mortality. These, however, are not entirely consistent with estimates produced by Institute of Health Metrics and Evaluation (IHME) in Seattle, and it is important for these institutions to collaborate closely to avoid such discrepancies.

WHO, UNICEF, the World Bank, and the UN Statistical Division, among others, provide consistent health information. The regular World Health Reports, issued by the WHO since 1995, the World Development Report of the World Bank (very notably the 1993 report on burden of disease) and the GBD Report 1990 (published in 1996) are major examples of such reporting. These traditional data providers have been joined by many other players in the past decade, particularly those who

operate using complex estimation methods for burden of disease, such as the IHME based in Seattle, USA, which uses the burden of disease approach to estimate DALYs for all countries in the world. Numerous other consortia and commissions, such as the Lancet Commission on Investing in Health (Jamison et al., 2013) have also entered the stage providing and appraising health information.

Countries in the developing world will need international support to build institutions and health management information systems that can produce accurate, unbiased data. For population health this means building national statistical systems and improving not only the measurement of fundamental statistics such as births and deaths and levels of mortality, but also intersectoral data with high relevance to health such as economic growth and poverty, taxes and trade, the environment, and education (Center for Global Development and The African Population and Health Research Center, 2014). As developing countries expand their health systems, metrics that measure quality of care are also needed. Though tools such as the Health Care Quality Indicators project of the OECD and the WHO Performance Assessment Tool for Quality Improvement in Hospitals are helpful, others will need to be developed by making use of new technologies.

Management by objectives has become a key feature of global health programs push for data and health information systems. The development of comprehensive global monitoring frameworks for a range of diseases, which include a set of targets and indicators to track progress toward global and national goals, are becoming a standard procedure. Most recently, a framework was adopted to monitor national and global progress in implementing strategies for the prevention and control of NCDs. This includes monitoring exposures (risk factors and social determinants), outcomes (morbidity and mortality), and health systems capacity and response to health crises (Ijaz et al., 2012). In a similar vein, a wide range of other focused global programs have set targets to measure impact and success. Starting with the goals set for HIV AIDS, tuberculosis, and malaria in the Millennium Development Goals further targets have been set by the global tuberculosis strategy and the global malaria action plan. The global health community has also set goals for the elimination and eradication of a range of diseases, at present for polio eradication. As this program comes to a close, a complex system of surveillance is required in areas at particular risk of missed transmission including targeted community searches, six-monthly active case searches, and case searches during vaccination (Global Polio Eradication Initiative, 2013).

New Developments and Challenges

As the move toward improving the health information systems in the developing world gathers pace, new opportunities, and challenges have emerged. Opportunities consist of the fact that better health information systems can help countries reach critical objectives in health care and the global community to achieve common goals. Better surveillance can enable rapid response to health crises and bigger sets of data have the potential to provide a better understanding of health and its determinants. Challenges arise from concerns that more and more health data are being gathered by corporations, both in developed and developing countries. Consequently, to prevent misuse of data, more policies need to be directed toward the ethics of data collection, storage, use and destruction, security, and consent (Harrison, 2014).

Another new development is the creation of digital open access platforms. Such a platform is the global health research process map by the Global Health Network, which allows for sharing of research and information (The Global Health Network, 2014).

New visualization tools have been a major breakthrough in recent years to display data. The Global Health Observatory at WHO headquarters and the WHO Regional Office for Europe provide numerous atlas-based, and easy-to-use visualization options, including the Atlas of Inequalities in Europe. IHME in Seattle has an altogether different but very effective range of visualization tools, which require a more complex IT setup than those provided by WHO. Scientists, policy-makers, and the general public all have immediate access to these tools. In addition, 'information about the information' or 'data about the data' are given to users to help them appraise the information; these 'metadata' are becoming more and more the standard in health information reporting. However, disaggregation of data by age, sex, vulnerable groups, etc, is still lacking in many countries (and particularly at the subnational level) and is a very important element for the analysis of inequalities in populations.

The provision of 'real-time' data, that is, the collection, analysis, and display of data as they are produced is still some time away from practical application despite the revolution in eHealth and IT solutions. This is largely a reflection of the need for quality assessment of the data, which often requires 'cleaning up' due to data entry errors or misclassification. As a result, time lags or delays invariably occur and are required to ensure that the user only receives correct information.

The fundamental challenge in the current era of global health will not be technological, but rather be better governance and accountability for common health goals by the wide range of public and private actors. The greatest global and national challenge at hand is failing to act on the data that could save lives and improve health.

Abstract

In comparative research, obtaining valid and reliable data is more challenging than in most other research techniques in social sciences. Presenting the European Values Study as an example, this article sketches how the field has established comparative databases that increasingly address these challenges. Examples of selected comparative databases at different analytical levels (micro versus macro) and from different source types (academic versus official statistics versus nongovernmental organization) are provided. A brief outlook on remaining and newly arising methodological and organizational issues concludes this article.

Introduction

The Need for Comparative Research

Many research questions in the social sciences are of comparative nature, explicitly or implicitly: investigating the different effects of national welfare regimes on inequality or the effects of particular electoral systems on the extent of participation obviously requires that researchers observe variation across different institutions, and across potential explanatory factors. Sufficient variation across institutional settings can be found either by looking at different countries, regions, and cultural areas, or by looking at changing institutions in the same country over long time spans. Ultimately, the dimensions of time and of space provide the variation needed for empirical testing (Przeworski and Teune, 1970). If both are combined, a space-by-time matrix is obtained. This is useful for assessing developmental hypotheses that predict particular trajectories over time, depending on characteristics that vary on the 'space' dimension (Franklin and Wlezien, 2002). In a nutshell, empirical research at the level of societies almost always requires comparisons across different societies, and across different states of one and the same society.

Macro and Micro Data

Data that describe units at the level of nations or societies are commonly referred to as macro data. Beyond singular questions about particular institutional arrangements etc., analyses of macro data are relevant to testing many 'grand' sociological, political, or economic theories, for example, theories dealing with welfare or political regime types, modernization, and economic development. But data at the individual- or microlevel are often equally relevant in informing 'grand' theories. Value change, secularization, and political processes with citizen involvement all have in common that many of their empirical statements directly refer to the microlevel, therefore making micro data indispensable for empirical work. It is typical for sociological and political theories to touch on both levels, so the question of empirically depicting connections between the macro- and microlevel is one of the most relevant (Coleman, 1990; Erikson, 2002). But even pure microlevel theories (such as psychological theories on personality traits or economic theories on labor-market behavior) benefit from empirical underpinnings in a comparative perspective, because cross-cultural comparisons of within-country microlevel mechanisms speak of the degree of universality that such theories can claim (or not).

Data and methodologies have long not been up to par with the needs of theories that claim an international or even universal scope. Many early comparative studies displayed a certain arbitrariness in the selection of the usually few macrounits they observed and compared, simply because there were no other options for obtaining comparative data but using personal networks or other idiosyncratic options. The independently collected data from these macrounits were then analyzed as a set of parallel case studies (see Kohn (1989) as an example of the genesis of data collection options and the analysis design). The increasing availability of systematically collected comparative data has allowed researchers to match theoretical scope and empirical underpinnings much better, so that certain country-level characteristics can be analyzed for all countries. Often, matching microlevel data are there as well, to build a full multilevel analysis.

Methodology itself has moved from a parallel case study approach to formalized methods looking for statistical confirmation at all levels of observation, with methods such as cross-sectional time series analysis or multilevel regression models. Where still only small numbers of cases are present, the method of qualitative comparative analysis (Ragin, 1994) has become a popular option.

Of course, the development of analytical approaches and the availability of data are tightly wed. Improving the database for comparative research increases the opportunities for such research, and comparative research at the society level in turn contributes to extending the database. Accordingly, both the use of existing databases and the creation of new comparative data have become routine exercises for research communities. This article will therefore only present a limited and intentionally heterogeneous selection from the wealth of existing comparative databases, trying to identify some typical aspects on a few examples that are more deeply elaborated. Readers in need of more complete coverage should consult the relevant cross-references.

Comparative Databases: Definition

By the term *database*, the authors refer to any data file or set of data files that has/have been systematically prepared to support empirical research. A *comparative database* is therefore any database that helps comparative research as described above, by allowing a comparison across the boundaries of at least two units at the macrolevel, regardless of the data itself being micro- or macrolevel data. Under this definition, almost any research project that collects, merges, or edits data to be used in comparative analyses constitutes a new database. Therefore in the remainder of this article, the authors discuss only comparative databases that are intended to serve as research infrastructure, accessible not only to the person(s) that compiled them but also to a broader community of researchers. As the compilation of comparative data almost always requires some form of international collaboration, building such a database usually constitutes a major investment that is more easily justified when wide and enduring usage of the data can be expected. This commonly implies that such databases should be, and often are, used for a variety of purposes and research questions rather than for singular, one-off projects. It also implies that the organizational framework for providing access to the data is geared to a longer time frame.

Starting Ground and Some Examples

Availability of Data

The data that feed into comparative databases come from many sources that can be grouped into academic data collection efforts, national and supranational agencies, and Nongovernmental Organizations (NGOs). Nonacademic agencies such as statistical offices, the Organisation for Economic Co-operation and Development (OECD), different branches of the United Nations (UN), or NGOs provide access to their data in order to meet their legal mission and to support their policy goals. Consequently, macro data from these organizations, e.g., aggregate figures on national economic performance or levels of health care provision, have for decades been accessible to research. If restrictions existed, they mainly lay in the area of lacking documentation, or in data structures that were much less suitable for research than for administrative purposes. Within academic research, in most disciplines, sharing data with third parties has been less common, and only very recently, research funding agencies make the provision of access to the collected data a binding obligation in their grant agreements. However, social sciences have always been among the pioneers with respect to 'data sharing.' On the international level, especially a number of early comparative social science projects were forerunners for establishing research databases as infrastructures, with sociology and political sciences being served by the same institutions and partly the same data (1,2).

Obtaining Comparative Macro Data

With regard to macro data, in the early times, data sharing took the form of providing tables and lists in printed publications, as exemplified in one of the most visible early databases, the data on the stability and capabilities of states coded and compiled by Karl W. Deutsch (1960). In that heavily cited example, only 11 quantifiable characteristics of states are coded that pertain to one single point in time, mostly taken from various UN publications of the 1950s. This already signifies one typical feature of quantitative comparative macro databases: behind the final data outcomes, there are long chains of production, often from surveys administered by national statistical offices, over aggregations at national level, to further aggregations done at supranational level, to compilations and selections done for research projects. In contrast to that, macro data that are not analytical aggregates of micro data can be of a more direct observational and partly qualitative nature. Expert judgments of published documents and media reports inform projects like the Polity database that was founded in the 1960s and is now in its fourth development stage 'Polity IV,' (Marshall and Gurr, 2012). The Polity databases compile data about the political stability or fragility of states, the occurrence of violent conflict, and the state-level factors contributing to both. Both the microaggregation and the expert assessment types of project have in common that – at least in their nascent phase – they can still be within the realm of individual researchers or small teams because the compilation of already published quantitative data or document analysis do not always require systematic international collaboration and large teams.

Obtaining Comparative Micro Data

This contrasts with projects that collect data at the microlevel in a comparative fashion. Conducting comparative surveys has always been a major effort in terms of coordination and collaboration, not the least part of that being raising funds for fieldwork from the respective national funders in a coordinated fashion.

With dispersed funding structures and general organizational overhead being major barriers for the implementation of comparative surveys, it is no surprise that the first examples of comparative micro data collection efforts either used a very loose organizational framework or were spin-offs from other work conducted by sufficiently resourceful agencies. Probably the first instance of a (partly) comparative survey series were the so-called United States Information Agency (USIA) surveys, conducted in France, Italy, the United Kingdom, and West Germany between 1952 and 1976. They were centrally organized and funded, avoiding many problems in international coordination. The carrying agency was the USIA that basically pursued the goal to inform US foreign policy about strategically relevant attitudes of the populations in other countries (the USIA data are available through the GESIS Data Archive). The first truly academic comparative projects are often reported to have been the study on 'Patterns of Human Concerns' (3) in 14 countries across the world, the 'Civic Culture Study' (Almond and Verba), and the 'International Time Use Survey' (4). More complete overviews can be found in Refs. 1, 5, and 2. Even this short list of studies covered a wide scope of topics: the different general expectations that people had for the future, the orientations they had toward political participation, the ways they allocated time to everyday activities. One common driving feature in that heterogeneity was the researchers' interest to gain an initial insight into the degree and quality of international

diversity in the human condition – how different or similar are the lives of humans in different parts of the world? After this need was increasingly satisfied, the following two decades saw a slowly increasing degree of ambition and rigor in the implementation of comparative surveys. The first comparative data collection projects in the 1960s had largely collected data in those places where the opportunities for collaboration happened to be, whereas the next wave saw some efforts that were striving for completeness of coverage in some sense, most notably the European Communities Study, which in 1970 was installed as the forerunner of the Eurobarometers of the European Union. In 1973, it was extended to include all member countries of the European Community at that time, in order to better fulfill its intended main purpose of monitoring the state of European integration in the eyes of the public, and as input for European policy makers. The model of the Eurobarometer – which is repeated in regular intervals and served to provide the empirical base for Inglehart's famous hypothesis of the 'Silent Revolution' – also makes clear how comparative survey series can become tools for the analysis of societal change over time, provided that at least some parts of the questionnaires are standardized (Inglehart, 1977).

Data Archives

With these comparative surveys constituting relatively large investments, the community from the beginning strove to establish mechanisms for wide access by researchers and found these in the emerging survey data archives (Mochmann, 2008). Although institutions such as the Inter-University Consortium for Political and Social Research (ICPSR, University of Michigan, founded in 1961) or the Central Archive for Social Research (in Cologne, Germany, founded in 1960, now GESIS Data Archive for the Social Sciences) were organizations with a primarily national foundation and purpose, they provided basic services for archiving and dissemination that made the wide and continuing use of the comparative data sets from sociology and political science possible. They thus added a dimension of long-term sustainability to the comparative projects without which the cumulative expansion of these would not have been possible. One aspect of this is the built-in institutional stability of the archives, which is achieved either by a network-based funding (as for the ICPSR) or by long-term government funding (as for the GESIS archive and several other European data archives).

The European Values Study

Creation of the European Values Study

The step to data collection projects becoming long-standing infrastructures with an identity of their own is easiest when the data access providers come to play an active role in the overall projects. The authors use the case(s) of the European Values Study (EVS) and the World Values Survey (WVS) as illustrative examples for the trajectories that large infrastructural projects have taken over the past decades, and how they adapted to changing environments. The EVS has its origins in the late 1970s and was started from the Universities of Tilburg and Leuven as a project to study values and norms in European societies. Its first survey was fielded in 1981 in 14 European countries, but also in Canada and the United States. The study eventually evolved into one of the few really long-lasting surveys: the latest survey was fielded in 2008 in all European countries with a population over 100 000.

In the first survey from 1981, the main value domains studied were family, work, religion, politics, society, Europe, and well-being. The survey was coordinated by Gallup from London. Face-to-face interviews were held with random samples of at least a size of 1000. Identical (translated) questionnaires were used. Data were made available for the public through the data archive at the University of Essex (now UK Data Archive).

The second round of surveys was held in 1990 and there was an expansion to many countries in Eastern Europe (partly coordinated by Hans-Dieter Klingemann). The timing of this survey coincided with the fall of the Wall and actually accounted for a 'zero measurement' of the Eastern European societies at the moment of the decline of the communist regimes. The 1990 round was coordinated by the Institut für Demoskopie at Allensbach am Bodensee. From this wave on, National Program Directors got a more important coordinating role. The data were archived at the Steinmetz Archive in Amsterdam (now Data Archiving and Networked Services (DANS)).

Creation of the WVS

During this period, there was also an extension of the (almost equivalent) questionnaire to non-European countries. Under the direction of Ronald Inglehart, surveys were held in many countries. These surveys were the upswing to the creation of the WVS. From 1995 on WVS had its own organization and conducted surveys at 5-year intervals (1995, 2000, 2005, and 2010). Originally, WVS had its data archived at ICPSR in Ann Arbor (Michigan); later the primary data archive became ASEP/JDS in Madrid.

At the turn of the millennium, there were (independent) rounds of surveys of both the EVS and WVS. In total, about 70 countries were surveyed, yielding a big comparable database, because there was still a notable overlap in the questionnaires of EVS and WVS. From this time on, GESIS was the primary data archive for EVS and ASEP/JDS for WVS. One important issue now became the distribution of the data in a unified format. In cooperation EVS and WVS created a common dictionary (codebook) that covered all questions and variables used in any of the values surveys since 1980. This prepared the publication of the first integrated values surveys database that made the joint data set available to the academic community. Through online access platforms maintained by the respective Data Archives, the underlying documentation also became available: the questionnaires used in all the countries with the different languages, the methodological reports containing information on sampling, nonresponse, etc.

Evolution of the EVS

When planning the most recent, fourth round of EVS surveys for 2008, new developments in the data infrastructure were the basis. In the EVS 1999 survey, there already had been an extension of topics for the survey: solidarity (e.g., with the elderly, disabled, or immigrants), social capital (networks, trust,

civism), democracy, and work ethics. An agreement between EVS and WVS was developed that both organizations would take care of the publication of their own data collections, but that they would safeguard the possibility to easily match the two study-specific longitudinal data sets. In practice, this means that there is agreement about the semantic structure of the integrated database and the labeling of the variables in a unique way.

In 2008, the database for EVS contained all (47) European countries. After data collection, analysis-ready data files as well as the original data files and all kinds of documentation on methodological issues were stored in the data archive to be made publicly available. Besides an Integrated Data File for simultaneous analysis of all countries, this includes separate data files for all countries and a new EVS longitudinal data file.

In retrospect, a great development is seen in the questionnaire construction, sampling, fielding, standardizing of variables to match international classifications (NUTS, ISCO, ISCED, ISO-language), and archiving of the data. An event that illustrates the typical shortcomings in the 1980s is how the region information on the respondents was lost in one country's data. In 1981, information had been collected and stored with punch cards and on paper. Later, data was mainly stored on a varied collection of tapes or hard disks, with the documentation being held in unstructured formats. When the data were transferred to newer information carriers, the original respondent numbers that also contained a region identifier were replaced by sequential ID numbers, thus deleting the regional information. Improvements in advance coordination, monitoring, and archiving processes greatly reduced the number of such problems over the consecutive waves of EVS. The last survey of 2008 can now be seen as a state-of-the-art model for survey research data dissemination, since all (*meta*-) data currently regarded as necessary for methodologically sound analyses are easily available through web platforms. Efforts have also been made to integrate the existing data over time, and with the global data of the WVS. Thus, there is a longitudinal data file that maintains all overlapping information from all EVS survey waves, and there are tools to aid the merging of this file with the analogous WVS longitudinal data file. A precondition for this was that both the EVS and the WVS first collated all their survey waves internally within their respective data archives, creating single points of access for the wider research community. Ultimately, global-level data of the WVS and European-level data of the EVS can be analyzed together, providing a wide view over time and space.

The organizational trajectories of EVS and WVS showcase some interesting aspects of sustainable infrastructures. Beginning with the initiative (and funding) of a rather small core group of researchers, both projects established and extended networks of cooperators for national data collection. Importantly, both projects relied on (different, and for some time changing) data service providers to make analysis-ready research data openly available to the scientific community. Parallel to that, both projects of course produced research output in the form of publications, maintained websites, organized conferences, etc. For these projects it was a major building block of their current, well-defined public identity that they managed to produce research output of their own and to provide access to the data for others under the same 'brand names.' In both cases, this was achieved through an increasingly close and permanent relationship between primary researchers and the providers of infrastructural services. Very similar collaborative structures carry other ongoing programs such as the European Social Survey (ESS), the International Social Survey Programme (ISSP), the Comparative Study of Electoral Systems (CSES), and various international 'Barometer'-type programs (see below).

Selected Individual- or Household-Level Databases

General comparative survey programs are probably the most important source of individual-level data for sociological and political science research. Per definition as a 'program,' they collect data in regular intervals, often in (bi-) annual patterns. Being 'general' means that they address multiple research purposes by prescribing a set of basic standard measures for each survey instance (usually also including variables other than mere demographic information), which are then combined with topical modules that vary across survey instances.

International Social Survey Programme

The first truly international survey program – in that it has no proclaimed regional focus but is open to worldwide participation – is the ISSP. The ISSP was started in 1984 as a voluntary network of only four research organizations. As of 2013, ISSP has 48 members across the world and continues to expand. ISSP performs annual surveys organized into rotating topical 'modules,' so that each topical module is repeated after roughly 10 years. As two-thirds of the module questionnaires are replications of the previous module on the same topic, ISSP automatically builds cross-sectional time series over long time spans, creating a tool to monitor long-term societal change on topics such as religion, social inequality, citizenship, and social networks, to name only a few modules. Although countries or regions such as South Africa, Palestine, China, and India are now represented, ISSP is far from achieving universal coverage of the world's nations. With the national surveys being self-funded, only countries with sufficiently developed local social research institutions are able to participate. This explains the sparse coverage of developing countries.

Gallup World Poll

The only general purpose survey program that actually provides almost exhaustive coverage of the world's nations (160) is a primarily commercial endeavor. The 'Gallup World Poll' was created in 2005–06 and is designed to inform political decision makers on international societal trends such as happiness, migration, perception of corruption, and various others, for which it has solid foundations in substantive and methodological research. The data are currently available to academic research under individually negotiated conditions.

Eurobarometer

Other general comparative programs all have a regional focus. The Eurobarometer series is run since the early 1970s by the European Commission. It covers the member countries of the

European Union, sometimes also candidates for the European Union. Thus, it has expanded its geographical horizon along with the expansion of the political union. Thematically, Eurobarometers deal with all citizen attitudes and behaviors of political or societal relevance to EU policies. The 'Standard Eurobarometers,' fielded twice per year, have an ongoing set of questions on attitudes toward European integration, but add changing focus topics. 'Special' and 'Flash Eurobarometers' are conducted in irregular patterns to address short-term issues. All data are in the public domain and made available through the GESIS Data Archive.

European Social Survey

A fully academic project is the ESS, which since 2002 monitors societal and attitudinal change in Europe to inform social research. It is supported as a research infrastructure project by various member states of the European Union. ESS follows the ISSP model of a mix in standard and rotating contents in several respects, but applies a biannual data collection scheme and puts a very strong emphasis on methodological rigor in fieldwork, measurement methods, and international harmonization. The data are openly available through a website maintained by the Norwegian Social Science Data Archive. The site also offers rich material for academic training.

Other Barometer-Type Surveys

Outside Europe, researchers in several world regions have begun to install region-specific attitude monitoring programs, most of which specifically look at topics of democracy, citizenship, governance, etc. The Latinobarometro, the Asia Barometer, the Afrobarometer, and the Arab Barometer all follow a similar model and cooperate under the network of the Global Barometers initiative. Data access is usually possible for nonparticipants in these projects, too, but it is less standardized than with the aforementioned projects.

World Health Organization Surveys

Among the comparative survey programs directed at specific research topics, two large surveys conducted by the World Health Organization (WHO) deserve mentioning, although they are not ongoing programs. The Multi-country Survey Study of 2000–01 and the World Health Survey of 2002–04 tap into individual health issues and health service availability. Although not all microlevel country data sets are accessible, data access is generally transparent, and the inclusion of many third-world countries makes these surveys unique. This is one of the rare cases where an international organization does make at least some of the micro data behind aggregate statistics (see below for WHO aggregate data) available. For Europe, the health topic is now addressed by a specialized ongoing program Survey of Health, Aging and Retirement in Europe (SHARE), with an almost exclusive focus on the population older than 50 years.

Comparative Study of Electoral Systems

Topical programs with a more academic orientation include the EVS and WVS described above. The other specific topic besides values that finds regular coverage in survey programs is elections and democratic development. Especially the CSES constitutes an unprecedented effort to collect data not only on citizens' attitudes but also on several levels of polities, thus providing a basis for understanding the democratic process in a more complete way. Macro data matching specific research questions are collected along with the survey data. Data are collected shortly after national elections, which binds the timing of national surveys to the respective electoral cycles and enforces a wide time bracket for a set of comparative surveys. CSES strives for wide international coverage, but has to rely on the ability of national institutions to participate in one of the survey waves. Since the first wave from 1996 to 2001, CSES has completed two further waves (modules) and is currently fielding a fourth wave of surveys. Similar in their multilevel design, but focused only on elections to the European parliament are the European Election Studies.

Topical Macro Databases from Academic Projects

Historically, most comparative analyses were done on the basis of macro data, comparing societies or states as units. These early analyses were commonly based on published statistics, whereas research questions for which no official data are available – political system attributes, ethnical or political conflict, corruption, and subjective happiness – require that researchers collect their own macro data.

Correlates of War

The area of militarized conflict is thoroughly covered by the Correlates of War (CoW) project, which accumulates close to 20 separate data sets on risk factors of wars (internal and external armed conflicts) such as cultural differences, colonial history, trade data, etc., and, trivially but necessary, the presence of shared borders between states. CoW, founded in 1963 at the University of Michigan, is now maintained by a network of scholars who regularly update the individual databases following central guidelines. CoW data can often be linked to other macro data sets, for example, the Minorities at Risk (MAR) project initiated by Ted Robert Gurr. The MAR database presently contains information such as minority groups' religious orientation, geographical dispersion, degree of distinctiveness from the plurality, and the degree of discrimination on some 280 minority groups involved in political conflict, over a time span from 1945 to 2003.

Transparency International Index

Corruption shall be listed as the final item in this short list of databases on deficiencies of polities. The corruption index produced by Transparency International (a charitable foundation) is based on a mix of expert judgments and surveys and provides corruption rankings of nation-states in regular intervals.

The 'Polity' Projects, and 'IDEA'

Partly matching the individual-level electoral studies described before, political science collects macrolevel data. At the most

general level, the series of Polity projects (I–IV) (again initiated by Gurr) distinguishes states by their levels of democracy versus autocracy, and describes their changes over time. Polity has received funding from US government agencies under the expectation of informing foreign policies, but the data have always been publicly accessible. Looking at democracies alone, core variables of electoral processes – electoral system design, voter turnout, and political finances – are compiled and reported by the International IDEA project. IDEA (International Institute for Democracy and Electoral Assistance) is an intergovernmental organization to support the development of democracy worldwide. Given the variety of electoral systems and the unreliability of certain official statistics, even collecting and harmonizing the apparently straightforward comparative voter turnout data appears simple on the surface only.

Comparative Manifestoes Project

The Comparative Manifestoes Project looks at the content side of political competition in democracies. It collects and codes the texts of political program statements expressed by political parties prior to elections. The coding of manifestoes is performed intellectually, counting positive or negative statements about a predefined list of political topics. This allows for later matching proclaimed party positions with issue preferences in the electorate, or with policy outcomes after the elections.

World Database of Happiness

Although many of the research-driven databases mentioned above are oriented toward political science, other areas are certainly not void of such databases. An example that is equally relevant for economics, sociology, and psychology is the collection on subjective happiness that was compiled under the direction of Ruut Veenhoven. The World Database of Happiness is a special case insofar that it is a compendium of research in the sense of both data and publications. Happiness research necessarily builds on individual-level data, which is not directly available from the Happiness Database website. But the site does provide collected macrolevel aggregates of surveys, systematically ordered to provide time series at the national level. This allows for correlating national happiness levels with other national-level measures, especially such as economic welfare.

World Religion Database

Religion is another area on which official statistical information is available only at national levels and in ways that are not easy to standardize for international comparison. The most complete and continuously maintained source on religions across the world of which the authors are aware, the World Religion Database, grants access to its information on the populations of the world religions, their regional distribution, etc., only under a subscription model. Other databases are available but produce data of lower density.

European Data Center for Work and Welfare

An interesting example of a different kind is the 'European Data Center for Work and Welfare' (EDAC, www.edac.eu). EDAC constitutes a 'meta shell,' i.e., an organized collection of descriptions of topical databases, along with access information. EDAC is a website established in 2006 as an EU-supported initiative at Tilburg University. After this network ended in 2011, EDAC continued as a consortium hosted at CEPS-INSTEAD in Luxembourg and at the University of Leuven. The goal of the website is to supply information and (in)direct access to more than 500 sources in the field of work, care, and welfare. The unique selling point is the structured overview on the start page where one can choose between (1) comparative data, (2) national data, (3) international repositories, and (4) Europe. In the second stage, an overview of the relevant databases or repositories and search engines is provided. It is also possible to do a keyword-based free-text search. The main benefit for end users is obviously that the search for data sources is prestructured and guided. Even though no maintenance of actual research databases is required for this meta shell type of facility, the information collected in the shell itself requires considerable ongoing curation for keeping data and sources up-to-date and in touch with new research developments.

Supranational Organizations and International Official Statistics Data

Supranational organizations, especially the UN with their subdivisions, the World Bank, and the OECD, are major players in the provision of comparative macro data. With evidence-based policy making being part of their mission, they maintain research departments that have continuously improved the access of the wider research community to data collected under their auspices. This nowadays often includes access to micro data of many large official surveys that traditionally would have been reported only as macro aggregates.

One case in point is the International Household Surveys Network (IHSN). IHSN is a joint initiative of UN agencies, World Bank, and others, providing documentation and access for many household-level official statistics surveys, especially those that were used as input for comparative analyses performed at the listed institutions. This has led to a rich catalog of household surveys, with a focus on developing countries. Similarly, the WHO maintains a repository called 'Global Health Observatory.' This holds not only over 50 macro data sets on population-level health-related topics but also numerous individual-level survey data sets.

While supranational bodies with political or administrative objectives have a natural interest in using and producing comparative data, their national counterparts – usually statistical offices – naturally have national priorities when handling data. Thus, international comparability is often a secondary aspect. Still, statistical offices usually possess the most comprehensive and reliable data collections in their respective country, especially as they collect census data. An outstanding achievement is the 'Integrated Public Use Microdata Series, International' (IPUMS International). IPUMS is a long-standing project at the University of Minnesota with multiple sources of funding and support that compiles and harmonizes national, fully-anonymized-level census data and makes them

available for researchers in a uniquely accessible and well-documented way.

A more typical output from official statistics is almost all data that tap into topics of economic activities and developmental status. OECD and the World Bank aggregate national statistics to supranational levels. By virtue of the administrative integration rules of the European Union, the 'European Statistical System' has a special position here, because it obliges national statistical offices of EU countries to supply pre-harmonized data to the central European statistical office Eurostat. Eurostat offers much of these data to researchers, but for micro data access considerable handling fees may apply.

Finally, supranational agencies or NGOs sometimes produce composite indices for which several of the aforementioned sources are selected and joined. A very prominent example is the 'Human Development Index' (HDI), which is a key figure annually produced by the United Nations Human Development Programme (since 1990). It is meant to convey concise information about the economic and societal development at the national level, with the main purpose being to give a general picture of the general living conditions in a given country at a given time. For this, it collates average country-level information on life expectancy, exposition to education, and economic output per capita. Extended versions of the HDI adapted to reflect economic inequality and gender biases have been added in the meantime. Even for the core HDI, computation rules are constantly revised and a fresh, backward-looking calculation for HDI scores is performed with each new publication of the index.

Current Problems and Future Perspectives

Methodological Problems

Typical methodological problems of comparative databases are, naturally, those at the core of all comparative research. Data from different sources were possibly collected using different methods, under different conditions, and in different cultural contexts. With all these differences, there is no certainty that the data describe the same kind of reality across sources. If this is not demonstrably the case, comparisons might not bring out valid substantive differences between countries, but instead produce biased results. The problem of comparability becomes most evident when large amounts of such data are concentrated in one system. The situation is easiest if 'ex-ante harmonization' has been applied, meaning that the data collection process has been intentionally designed to produce comparable results, e.g., by making sure that question formulations in different languages actually convey the same message to respondents in the respective countries. Even though this does not guarantee immediate comparability, ex-ante harmonization is the best base for achieving it.

However, many microlevel databases and, by virtue of their construction, practically all macrolevel databases consist of ex-post harmonized data. Creators of comparative databases using ex-post harmonization are continuously making judgments whether information item 1 from country A is similar enough to information item 2 from country B to appear in the same column of a raw data table without further treatment, or if particular harmonization steps should be taken, or if a comparison should not be allowed at all. Is, for example, an apparently simple property such as the average household size sufficiently comparable between countries A and B if in country A only respondents in an age bracket from 21 to 90 were surveyed, whereas in country B there was no explicit age bracket (but perhaps that survey was limited to citizens of B, whereas the survey in country A included all residents)? What if one survey used a sample at the person level and the other one a sample at the household level? There often is no way of knowing if proper weights were used to correct this before the average figure entered into the database was computed. This kind of problem is prevalent not only in data from academic surveys but also in the data that are aggregated at international organizations, drawing on inputs from national statistical offices. A case in point is the Standardized World Income Inequality Database (SWIID, see link collection). It collates already existing macro data (Gini coefficients from various prestandardized sources) and performs additional harmonization steps to reduce remaining comparability steps, thereby markedly increasing the predictive value of inequality data versus external criterion variables. This kind of preparatory work by field experts is indispensable, as other users of such data are often not aware of the hidden complexities of data, either because they are either not well documented or because exploring the available documentation is deemed too time consuming.

Even beyond the issue of potential harmonization problems, further research on the quality of comparative macro data (including aggregated micro data) would seem in order. Where the measurement quality of microlevel data is extensively researched, very little systematic research exists that looks at the measurement properties of macro data. Two of the few exceptions are Munck and Verkuilen (2002) and Solt (2009).

A problem that limits the usefulness of many comparative databases for certain purposes is lacking coverage of some regions or countries. Such countries either do not have the resources to maintain data collection facilities or abstain from collecting or publishing reliable data for political reasons. For these reasons, academic survey research with microlevel data has almost no footing in Africa and for some regions in Asia, and only started building a database for South America and the former Eastern Bloc since the 1990s. And even in developed countries, there are almost no comparative panel (intra-individual longitudinal) data at the microlevel.

Organizational Challenges

Comparative databases tend to be the more valuable, the longer they have been maintained and extended in a consistent way – a task that has for several decades been managed by dedicated research data archives. With both comparative research and use of the Internet becoming ever more ubiquitous, a large number of diversified and also overlapping databases have become available through various kinds of Internet platforms that are not automatically attached to the traditional infrastructure providers. Potentially, any new comparative project that collects some data of its own, or manipulates existing data could be looked upon as a new database (King, 2011; Mochmann, 2008). It is technically easy to share these

data through the decentral means of the Internet. However, there are challenges arising from this: the publication of new data is only useful if the potential audience is also able to actually find the data, which is unlikely when it is dispersed over many platforms or websites, lacking central search facilities and standardized descriptors. Further, data maintained on platforms without continuous organizational backing may be at risk of loss, change, or manipulation, which would defeat the purpose of replicability that usually is regarded as one of the main benefits from the publication of research materials. Finally, using disparate data preparation and data distribution procedures is likely to make any particular data set less amenable for merging with other data sets to form an integrated database.

Research funders are increasingly aware of the organizational requirements for achieving long-term data availability and support the implementation of adequate national infrastructures. But how this will translate into infrastructures for comparative data is still unclear. The European Union has devised special organizational structures to take care of collaborative projects, the so-called European Research Infrastructure Consortia (ERIC). These are by design international and geared toward the provision of comparative data. The first ERICs in the Social Sciences were installed in 2012 and 2013 (SHARE, the ESS, and the Council of European Social Science Data Archives). Other regions of the world are following different approaches with predominantly national priorities. Presently, the only viable route to ease the building of comparative databases seems to call for voluntary cooperation among the agencies that collect and provide data, as OECD's Global Science Forum does (OECD Global Science Forum, 2013). The main method would be the early standardization of content descriptors and technical formats, as soon as possible in the data production workflow. With both content and technologies being subject to continuous development, this is likely to be a permanent chore.

Data Bases and Statistical Systems: Labor and Work

Constance Sorrentino, US Bureau of Labor Statistics, Washington, DC, USA

© 2015 Elsevier Ltd. All rights reserved.

This article is reproduced from the previous edition, volume 11, pp. 7511–7517, © 2001, Elsevier Ltd., with revisions made by the Editor.

Abstract

The article on 'Statistical Systems: Labor and Work' gives the readers an overview on national and international statistic programs on labor statistics. It comprises information on the most common topics and standard classifications of the social and economic issues of our time; it describes usual institutional frameworks to data collection, presentation and distribution to users. In addition, brief descriptions of comparative labor statistics programs, three international organizations, and a unique international microdatabase are presented.

Labor statistics represent a large body of information relevant to many of the social and economic issues of our time. They are used as indicators of how well the general economy is functioning and also as a basis for designing, implementing, and monitoring employment and social programs and policies. Labor statistics are generally part of a national statistical program and are interrelated with statistics in other fields, for example, with statistics on education, health, and production. International comparisons of labor statistics can help in assessing a country's economic performance relative to other countries (for example, by comparing unemployment rates and employment growth) and in evaluating the competitive position of a country in international trade (for example, by comparing productivity and labor cost trends).

Topics and Classifications

Article 1 of Labor Statistics Convention Number 160 of the International Labor Office (ILO) established in 1985, a minimum set of topics to be covered in official national labor statistics programs (ILO, 2000). The list is as follows:

1. economically active population, employment, where relevant unemployment, and, where possible, visible underemployment;
2. structure and distribution of the economically active population, for detailed analysis and to serve as benchmark data;
3. average earnings and hours of work (hours actually worked or hours paid for) and, where appropriate, time rates of wages and normal hours of work;
4. wage structure and distribution;
5. labor cost;
6. consumer price indices (CPIs);
7. household expenditure or, where appropriate, family expenditure and, where possible, household;
8. income or, where appropriate, family income;
9. occupational injuries and, as far as possible, occupational diseases; and
10. industrial disputes.

ILO convention 160 recommends that each member state (185 of the 193 UN member states are members of the ILO) "collect, compile, and publish basic labor statistics, which shall be progressively expanded in accordance with its resources to cover [these] subjects." The USA and most other developed nations collect and publish data for all subjects listed in Article 1. On the other hand, developing nations often do not yet have the full array of labor statistics. The publication Key Indicators of the Labour Market (KILM), first released in 1999 (Johnson et al., 1999), provides information about country-level data on currently 18 KILM in almost all countries of the world from 1980 to the latest available year. Deficiencies in the availability and timeliness of labor statistics are particularly apparent in Africa and parts of Asia. (See ILO, http://www.ilo.org/empelm/what/WCMS_114240/lang–en/index.htm.)

National Classifications

The presentation of labor statistics requires many distinctions or categories such as occupations and branch of economic activity. In order to facilitate data collection and analysis, these categories are organized into classifications. These are instruments that group together units of a similar kind, often in hierarchies, thus allowing for different degrees of detail to describe the characteristics in a systematic and simplified way. For example, in the USA, the Standard Occupational Classification (SOC) and the Standard Industrial Classification (SIC) have been the structures that define occupations and industries for many years. Such systems need periodic revision to keep up with the changing economy and to accommodate new industries and occupations. Revising the SOC System (2010), provides an account of the 2010 revision to the US occupational classification, a brief history of SOC system as well as a general time line for the 2018 revision.

The North American Industry Classification System (NAICS) represents a complete restructuring of the US SIC system (1997). This system was prepared jointly because the North American Free Trade Agreement of 1994 increased the need for comparable statistics from the USA, Canada, and Mexico. Each country can individualize the new system to meet its own needs, as long as data can be aggregated to the standard NAICS categories.

Other International Classifications

International standard classifications serve to enhance cross-national comparisons. The International Standard Industrial

Classification of all Economic Activities (ISIC) was established under the auspices of the United Nations, and the latest International Standard Classification of Occupations (known as ISCO-08) was established by the ILO's Tripartite Meeting of Experts on Labour Statistics on Updating the ISCO in 2007. Resolution concerning updating these classifications and correspondence tables with ISCO-88 are available on the ISCO Web site in English, French, and Spanish. (See ISCO, http://www.ilo.org/public/english/bureau/stat/isco/index.htm.) Countries often prepare concordances or 'crosswalks' that allow their national classifications to mesh with the international classifications.

International Concepts

The ILO's periodic International Conferences of Labor Statisticians have established resolutions and guidelines for the measurement of labor statistics (ILO, 2000), including recommendations on employment and unemployment statistics, statistics of labor costs, wage statistics, consumer price indexes, and strikes and lockouts. These guidelines serve as a model for countries trying to develop national statistics on the topic concerned and they also provide, to some extent, a benchmark for international comparisons. For example, ILO standards for measuring labor force, employment, and unemployment are followed by many countries. Varying interpretations of these guidelines, however, particularly with regard to different aspects of unemployment, create differences across countries that require adjustments to enhance comparability of unemployment rates (Sorrentino, 2000). The ILO recommendations and guidelines are available online at http://www.ilo.org/stat/lang–en/index.htm.

Institutional Framework

Labor statistics are primarily collected by governments rather than the private sector, although in some countries there has been a movement toward privatizing some data collections. In the USA, which has a decentralized statistical system, over 70 Federal agencies are engaged in the collection of statistics. The Bureau of Labor Statistics (BLS) in the US Department of Labor is the principal data-gathering agency of the US Federal Government in the broad field of labor economics. Most of the Bureau's data come from voluntary responses to surveys of businesses or households conducted by BLS staff, by the U.S. Census Bureau (under contract with BLS), or in conjunction with cooperating State and Federal agencies. Unlike the decentralized system of the USA, other countries tend to have central statistical offices, and the collection of labor statistics is accomplished within these national agencies. However, labor ministries often also play a role in the collection of labor statistics abroad. Several international organizations work in the realm of labor statistics, obtaining and publishing labor information from countries, providing technical assistance to member countries, and establishing conceptual guidelines. National agencies cooperate with the international organizations by transmitting the data requested on a regular basis and also for ad hoc studies. Major international organizations involved in labor statistics are discussed in Section International Comparisons.

Sources of Labor Statistics

Labor statistics are generally collected in censuses or sample surveys of households or business establishments, or processed on the basis of data resulting from administrative procedures of public agencies. Many of the major programs of the US BLS are based on sample surveys. For instance, the Current Population Survey (CPS) is a monthly survey based on a sample of about 72 000 households from 824 sample areas designed to measure demographic and labor force characteristics for the population of the United States; data are collected by computer-assisted personal and telephone interviews. The survey, sponsored jointly by the U.S. Census Bureau and the U.S. BLS, is the primary source of the national statistics on labor force, employment, and unemployment. About 70 countries conduct regular labor force surveys, on an annual, quarterly, or monthly basis. In January 2003, the CPS adopted the 2002 census industry and occupation classification systems, derived from the 2002 NAICS and the 2000 SOC System. (See Chapters 3 (pp. 1–15) and 4 (pp. 1–6) of *Current Population Survey, design and methodology* (Technical paper 66, October 2006 online at https://www.census.gov/prod/2006pubs/tp-66.pdf.)

Another major survey of BLS is the monthly Current Employment Statistics Survey. This survey is a sample of about 144 000 businesses and government agencies, representing approximately 554 000 individual worksites, and it provides employment, hours, and earnings data collected from payroll records of business establishments. Similar surveys are conducted by many other countries.

Labor statistics may also be based on administrative records. Although the primary purpose of administrative records is not the production of statistics, these systems provide a rich information source that has been exploited to varying degrees in different countries. Among the uses in the USA, administrative data from the unemployment insurance system are used in combination with CPS data to produce unemployment data for States, labor market areas, counties, and cities. In several European countries, employment office registrations are the primary monthly indicator of the labor market. This is likely to be the case in countries that do not have a monthly household survey as a source for unemployment statistics.

Some labor statistics are constructed by combining data from different sources. For example, industry labor productivity data (output per employee or per hour) require data on both labor input and business output. The labor input measures are generally constructed from a combination of hours data from labor force and establishment surveys, while the output components typically are based on national income and product accounts, which are derived from business establishment surveys.

Dissemination of Labor Statistics

Disseminating statistics means presenting and distributing the data to users in various forms and preparing analyses of the data. The BLS makes available the information it produces

through a broad publication program that includes news releases, periodicals, reports, and bulletins. Articles in the Monthly Labor Review present analyses of labor data. Some BLS material is available on magnetic tape, computer diskette, CD-ROM, and microfiche. Current BLS data, publications, and articles are also made available through the Internet. Other countries use similar methods of data dissemination.

The publications Major Programs of the BLS (1998) and the Handbook of Methods (1997; see the updated BLS Handbook of Methods online at http://stats.bls.gov/opub/hom/), as well as the BLS Web site noted in the bibliography, provide further information on the Bureau's programs and how to obtain BLS data. Links to the statistical offices of other countries as well as to international organizations are included on the BLS Web site.

In 1996, the International Monetary Fund established a Dissemination Standards Bulletin Board on a Web site to assist countries in following the best practices of dissemination of economic, financial, and sociodemographic data to the public. One of the aspects of this, the General Data Dissemination System (GDDS), guides countries in the provision of comprehensive, timely, accessible, and reliable data, and the site provides information on data produced and disseminated by participating member countries. The GDDS system is built around four dimensions – data characteristics, quality, access, and integrity. Information on the formats and titles of national statistical publications is included. The GDDS is a source of metadata (that is, descriptions of current practices on data concepts, sources, and methods) on labor statistics as well as on other types of economic statistics. The detailed metadata provide users with a tool to better assess the usefulness of the data for their own particular purposes.

International Comparisons

An international perspective can often enrich analysis of national labor markets, but such comparisons must be made with caution because statistical concepts and methods vary from country to country. Simply comparing national data across countries could lead to erroneous conclusions. The BLS and several 'international organizations derive meaningful comparisons by selecting a conceptual framework for comparative purposes; analyzing foreign statistical series; selecting those that most nearly match the desired concepts; and adjusting statistical series, where necessary and feasible, for greater intercountry comparability.

The BLS comparisons generally are based on the US concepts so that they will be on the conceptual basis most familiar to the US data users. Comparisons made by international organizations frequently are based on the international standards recommended by the ILO, discussed in Section 2.3. Brief descriptions of the comparative programs of the BLS, three international organizations, and a unique international microdatabase follow. Further information is available from their respective Web sites, cited in the bibliography.

Bureau of Labor Statistics

From its inception, BLS has published comparative information on labor conditions and developments abroad. Foreign labor research and statistical analyses have been undertaken because: (1) comparisons between US and foreign labor conditions shed light on the US economic performance relative to other nations; (2) comparisons provide information on the competitive position of the USA in foreign trade, which has an important influence on the US economy and employment; (3) information on labor conditions published by a majority of foreign countries is not readily available to the US labor representatives, employers, Government officials, and others, and frequently is not available in English; and (4) often, only an expert can judge the quality and comparability of foreign statistical data.

The BLS International Labor Comparisons (ILC) program has covered five key areas: (1) labor force, employment, and unemployment; (2) hourly compensation costs; (3) productivity and unit labor costs; (4) GDP per capita and per hour; and (5) consumer prices. Only the hourly compensation comparisons have covered 34 countries at various stages of development, whereas all other areas, the labor force (16 countries), productivity comparisons (19 countries), GDP per capita and per hour (20 countries), and consumer prices (16 countries), have given information only on major developed countries. However, according to the current announcement of the Conference Board (see ILC Tables at www.bls.gov/ilc), BLS has eliminated the ILC program due to across-the-board spending cuts termed 'sequestration.' For future release, BLS intends to produce ILC indicators similar to those done previously by BLS for future release. Outside the USA, national statistical agencies generally do not produce their own international comparisons.

They depend on the comparative work of the BLS as well as that of international bodies such as those described below http://www.ipetitions.com/petition/saveilc/.

International Labor Office

The ILO in Geneva plays a major role in the arena of international labor statistics. This agency's role has already been mentioned in terms of promoting the production of labor statistics and setting international standards for statistics. The worldwide scope of the ILO's membership ensures that this organization provides the most comprehensive geographic coverage among the international organizations involved in labor statistics.

The ILO has several publications or programs that provide varying degrees of comparable labor statistics. The annual *Yearbook of Labour Statistics* (ILO, 1999) is the most comprehensive source for worldwide labor statistics. The Yearbook compiles national labor data according to international classifications of industry and occupation, with annotations concerning deviations from these classifications, coverage, and sources. All data are supplied by the national statistical authorities. The Yearbook contains data on economically active population, employment, unemployment, hours of work, wages, labor cost, consumer prices, occupational injuries, and strikes and lockouts. Some statistics are presented as time series (the series usually cover the preceding 10 years), others are provided for only the latest year.

The ILO's program of ILO-Comparable labor force statistics takes the process a step further by making adjustments of the

labor force and unemployment data to ILO concepts for over 30 countries. Data from the ILO-Comparable program are available online (Lawrence, 1999) and are also used in the publication KILM (Johnson et al., 1999). The latter publication is well annotated concerning comparability issues for all of the 18 indicators provided.

Organization for Economic Cooperation and Development

The Paris-based Organization for Economic Cooperation and Development (OECD) comprises 34 member countries, most of which are the advanced countries in North America and Western Europe, as well as Australia, New Zealand, and Japan. In addition, some of the transition countries of Eastern and Central Europe, Mexico, and Korea became members of the OECD in the 1990s. Most OECD labor statistics cover the member countries only, but some series are being expanded to cover nonmember Asian and Latin American countries.

The main labor-related publications of the OECD are the annual and quarterly editions of Labour Force Statistics (1999). The annual publication compiles two decades of statistics, while the quarterly editions show selected data for the past 5 years. These publications provide statistics on key elements of the labor force, rather than on the broader range of labor statistics contained in the ILO Yearbook. Through the OECD's provision of extended time series, it is possible to identify structural changes that have taken place in the labor force of the countries with respect to gender, age, and economic activities. Data on part-time employment and duration of unemployment are included. The detailed statistics on employment are generally in conformity with the ISIC.

Another program of the OECD Harmonized unemployment rates, provides unemployment rates adjusted to ILO concepts for 34 member countries. The Harmonized rates are published in an annex to the aforementioned quarterly editions and they also are available from the OECD Web site. Additional labor statistics are published in the annual OECD Employment Outlook, expanding the range considerably to include special international analyses of training statistics, indicators of the degree of employment protection and regulation, trends in self-employment, income distribution, minimum wages and poverty, the transition from education to the labor market, trends in working hours, and workforce aging, to name some of the special studies. The OECD analyses pay careful attention to comparability and often contain annexes that explain the data comparison issues in detail.

Statistical Office of the European Communities (Eurostat)

Eurostat's main role is to process and publish comparable statistical information for the 28 member countries of the European Union (2014). Eurostat tries to arrive at a common statistical language that embraces concepts, methods, and statistical and technical standards. A significant portion of Eurostat's statistics relates to labor. The European Union Labour Force Survey (2013) is a joint effort by member states to coordinate their national surveys. The result is a detailed set of comparative data on employment, working time, and unemployment. Eurostat also publishes monthly harmonized unemployment rates for all member countries. Comparable data are critically important for the European Union because the Community's social funds are distributed according to a formula that includes unemployment as a significant component. Eurostat's Harmonized Indices of Consumer Prices (HICPs) are designed for international comparisons of consumer price inflation. The HICPs are the result of the collaboration between Eurostat and national statistical offices of member states on harmonizing the different methods used to compile price indices. The harmonization process has resulted in an improved quality of the indices. HICPs are not intended to replace national CPIs. Besides the labor force survey and CPI statistics, Eurostat also publishes results from its harmonized labor cost surveys and conducts a European household panel that allows for analysis of income, employment, social exclusion, health, education, and many other topics.

Luxembourg Income Study

The Luxembourg Income Study (LIS), begun in 1983, is a unique cooperative international research project with a membership that includes 25 countries on four continents. The project is funded mainly by the national science and social science research foundations of its member countries. LIS comprises a collection of household income survey sets of microdata (files of data on individual households) for cross-country research. A companion database established in 1993, is the Luxembourg Employment Study (LES). The data sets of LIS and LES have been harmonized in order to facilitate comparative studies. LIS and LES have become a rich source for comparative research in the areas of poverty and income distribution as well as labor market behavior. Moreover, these databases foster interdisciplinary research in the fields of economics, sociology, and political science. Researchers in member countries may use the LIS and LES databases at no charge, after signing a confidentiality agreement. Copies of the studies based on these databases are available from the LIS Web site.

Abstract

The breadth of information across a variety of jurisdictions makes subscription databases necessary to complete effective legal research. This article analyzes the utility of subscribing to one or more of the leading vendors and also suggests additional databases for anyone doing substantial American legal research. Particular emphasis is paid to the two leading vendors, Lexis and Westlaw.

United States' Legal System and Databases

The Importance of Legal Databases

Effective legal research in the United States' common law system requires mastery of both case law and statutes. To research the law on any given subject, a researcher must be able to identify statutes that address the legal issue. He or she must also locate and synthesize court decisions on the subject. The researcher must then form an argument about how previous court decisions should compel a court to rule on an unresolved legal claim. Although most trial, appellate, and Supreme Court decisions are published for public use, subscriptions to legal databases make researching legal issues easier and more effective. Without the assistance of a legal database, it is likely that a researcher will miss critical cases. Exhaustive searches are particularly important in common law jurisdictions.

Precedents and Stare Decisis

Concepts of 'precedent' and 'stare decisis' might be familiar to lawyers and students in civil law countries, but these issues are paramount in the United States' legal system. Courts reach their decisions based on precedent, or the cumulative body of cases previously decided by similar courts and tribunals. Sometimes a court must follow a precedent. For example, if the Supreme Court has interpreted a statute in a particular way, lower courts must adhere to that rule, even if they disagree with the Supreme Court's decision. The Supreme Court's precedents are thus described as 'controlling' authority. When researching a legal issue, one must be aware of and have access to all cases with precedential value. The influence of precedent is so strong that courts will rarely even reverse themselves. If an issue were to reappear at the Supreme Court, the Court would have the option of reversing its prior decision, but it usually adheres to its own precedent. This tradition of preserving precedents, called stare decisis, rests on the principle that similar cases should be decided consistently. Some precedents are not controlling, but merely persuasive. If a federal district court in Connecticut evaluates the same legal issue that a federal court in New York already addressed, the Connecticut court may elect to follow the prior decision, but it is not obligated to do so, because the prior decision occurred in another jurisdiction. The concept of persuasive authority means that one must be able to find relevant law outside of one's own jurisdiction. Often legal researchers use commercial vendors to search for such cases.

Commercial Vendors of Legal Databases

Traditionally, the commercial vendors Lexis and Westlaw competed for the attention of academics and practitioners; recently BloombergLaw has begun to challenge the supremacy of these two vendors. There are also a host of lower cost databases on the market (Justiss, 2011). Although many legal practitioners have access to only one of the primary vendors, most US law schools provide access to many and allow students and faculty to develop their own preferences. The interfaces of the two leading databases affect how users research (Jones, 2009), but the difference in content is not immediately obvious. Lexis and Westlaw's newest platforms, known respectively as LexisAdvance and WestlawNext, are two databases that demonstrate the utility of conducting legal research using a subscription database to conduct searches for case law, statutes, legislative history, dockets, and secondary sources. (Wheeler and Amrogi provide discussions about the differences between the products' newer models and their previous versions.)

The Value of Databases in Case Law

Organizational Benefits of Legal Databases

The common law system nearly requires a researcher to subscribe to one of the core legal databases to locate precedent. These databases publish decisions and link the user to prior decisions relied upon by a current case. They also provide a feature called the 'Table of Authorities,' which lists all cases cited in the opinion and indicates the depth of treatment each case received. The databases do the opposite as well, by providing access to cases that have cited to the case at hand. Finally, these databases work to distill legal issues so that one can find additional cases that touch upon the same legal issues. With centuries of precedent from a variety of jurisdictions, one benefits from legal databases that attempt to systematize case law and link to related issues and cases.

LexisAdvance

LexisAdvance accomplishes this through the use of several enhancements; two of the most important enhancements are 'headnotes' and 'Shepard's.'

Editors at Lexis do more than describe the subject matter of a case; they curate the materials by drilling down into each

discrete legal issue that appears in the body of a decision (Nevelow Mart, 2013). Editors or algorithms then assign each legal issue a 'headnote' (Nevelow Mart, 2010). Headnotes systematically organize law into categories and make it possible to find cases that are similarly categorized. The headnotes are buried within the text of the opinion, but they also appear at the very beginning of an opinion, which has the effect of creating an outline. Just as an opinion might have numerous headnotes, a particular passage in the opinion might receive several headnotes. Whenever possible, Lexis attempts to classify the headnotes into preexisting categories, which means a headnote will direct the reader to cases which have received similar headnotes.

If a passage receives multiple headnotes, the passage might reflect the convergence of two bodies of law. In other words, when looking at a headnote in a case about Family and Medical Leave, Lexis might indicate that this headnote can be classified under the path 'Labor and Employment > Leaves of Absences > Family and Medical Leaves > Remedies,' but it might also receive the path 'Constitutional Law > Equal Protection > Gender & Sex.' Clicking on the term 'remedies' might provide the user with a host of cases that differ greatly from the cases that would appear after clicking 'Gender & Sex,' but the Lexis editors have determined that the case in question belongs in both categories.

WestlawNext

The WestlawNext platform appears slightly different but also contains headnotes. Similarly, the editors take language from the opinion and attempt to place the language within the company's own proprietary digest, which classifies all points of law into headings and subheadings. Because the systems are unique to each vendor, not every point of law in a published case will receive the same treatment (Nevelow Mart, 2010). For example, there is nothing like 'Labor and Employment > Leaves of Absences > Family and Medical Leaves > Remedies,' which is a Lexis headnote path, on the WestlawNext platform. There is, however, a path of 'Labor and Employment > Time Off; Leave > Actions > Persons Protected and Entitled to Sue' on WestlawNext.

Westlaw created its digest system to bring order to the extraordinary body of case law (Doyle, 1992). Indeed, the terms above 'Labor and Employment > Time Off; Leave > Actions > Persons Protected and Entitled to Sue' are actually equipped with slightly more information, namely 'key numbers,' and direct links to those key numbers. In the WestlawNext system, points of law are classified within the larger framework of a digest. Any legal issue surrounding 'Labor and Employment' will, at a minimum, receive the digest number '231H,' which is how WestlawNext designates all Labor and Employment issues. Clicking on the '231H' link will direct a user toward all cases that Westlaw editors have identified as pertaining to labor and employment (**Figure 1**).

Points of law can be more specific than simply 'Labor and Employment,' as the path demonstrates. A researcher on WestlawNext who thinks a point of law in a case is important will probably be interested in clicking on the final key number that the point has received. Using the above example, a user can click on '231Hk384' which is the designation not just for labor and employment issues, but for cases uniquely described as relating to 'Persons Protected and Entitled to Sue' under the umbrella term of 'Actions' which falls under the umbrella term of 'Time Off; Leave.' WestlawNext refers to the identifier '231Hk384' as a 'key number.'

Clicking the '231Hk384' key brings a researcher into the digest and allows for further manipulation by jurisdiction. Furthermore, the results can be displayed to highlight cases that have received the most citation for that particular legal issue or by cases that have most recently cited that legal issue. One can limit results to require a particular keyword or date range.

Occasionally there will be no cases that have legal issues as specific as what the keycite path indicates. This might mean that a case is the first of its kind in its jurisdiction, or it might mean that the editors created an entirely new headnote path to deal with the case's unique legal issue. One problem with indexing is that editors have to anticipate future legal issues (Dabny, 1986). If the case is unique to one jurisdiction, both databases allow for the user to expand a search into one or more jurisdictions. This will retrieve precedent that might not bind a court, but could be considered persuasive. If there is no similar case in any jurisdiction, the visible digest path can be

Figure 1 Westlaw digest.

useful because a researcher can click on the key number one step above in the path's hierarchy. In the example above, one could click the key for the term 'Actions' or the key for the term 'Time Off; Leave.' Going up the chain in the digest path means there are more likely to be cases that have received that same key number.

The digest is available to all WestlawNext users by clicking the 'key numbers' link. It can be challenging to locate the particular legal issue by beginning with the digest, because not all users will be familiar with the terms that WestlawNext uses. It can often be easier to find cases by doing traditional keyword searches and looking for the key numbers in the headnotes of a relevant case.

Critical Services Provided by Both Platforms

Aside from headnotes, these databases offer other critical services. The databases' citation systems are particularly important. Citation systems enable researchers to identify whether a case (or a specific point of law within that case) remains good law. It directs the researcher toward cases that cite *to* the original decision. The editors at Lexis and Westlaw attempt to alert the reader to subsequent treatment of a case through the use of warning indicators. A case that has been overruled in its entirety or on a particular legal issue will receive a red stop sign after the case name on LexisAdvance. Additional icons indicate that points of law in a case were emboldened by later decisions or called into question. Sometimes, a later decision will disagree with the result in a particular case and overrule it directly. Because of the concept of stare decisis referenced earlier, these occurrences are rare. More commonly, a later decision will distinguish itself from the case at hand by identifying certain facts or features that might allow an alternative result. In this way, the legal principle of the original case might be limited to a smaller set of circumstances. On LexisAdvance, these cases will receive a yellow triangle, which indicates to the reader that the case might have particular limitations not detectable from the language in the opinion itself.

When looking at a case in LexisAdvance, the 'Shepardize' link accesses a screen that contains several important pieces of information: the Appellate History, Citing Decisions, Citing Law Reviews, Treatises, etc. (This article's discussion of law reviews, treatises, etc. appears in the Section entitled 'Secondary Sources.'; **Figure 2**.) The Appellate History directs

Figure 2 Lexis citing references.

a user toward different stages of a case throughout its appellate process. For example, someone who Shepardizes a Supreme Court case should be able to identify and retrieve decisions from the court of appeals as well as the trial court. In addition, LexisAdvance will point toward subsequent decisions that resulted from the Supreme Court's instructions. One can even visualize the appellate history by clicking on a 'map' function (Figure 3).

Clicking the 'Citing Decisions' tab brings the user into a field of subsequent decisions. It is simple to manipulate the results; for example, one might wish to see only cases that have treated the case negatively or have distinguished the case. Similarly, one might wish to eliminate all subsequent decisions outside of one's own jurisdiction. One field indicates how many opinions have been issued in each circuit, which can indicate that a circuit other than your own might have addressed similar legal issues or might provide a framework for your argument. Another option would be to require a case to have been published within a certain timeframe.

One particularly useful field is called 'discussion.' The discussion field describes subsequent cases by the amount of attention they pay to the case in question. WestlawNext uses one to four stars to indicate the depth of treatment, whereas LexisAdvance presents a bar (Figure 4). Cases that 'analyze' the opinion have all four bars filled, which indicates that the cases will devote nearly a full page of text elaborating on the opinion. Other options include 'Discussed' with three bars, 'mentioned' with two bars, and 'cited' with merely one bar. Discussed indicates an opinion has devoted at least an entire paragraph to the case, while 'mentioned' describes cases that reference the case with slightly more focus than a mere citation.

The WestlawNext model is quite similar in its citator function. WestlawNext calls this function 'KeyCite.' KeyCite has flags (red and yellow) that indicate at least one point of law in a particular case is no longer good or has been called into question. It also features depth of treatment stars, which indicate the amount of attention a citing case will pay toward the case in question. A user can filter by document type (including highest court in a jurisdiction or law review article), jurisdiction generally, depth of treatment, date, and using a keyword search, which can be accessed using the 'locate' feature.

Remarkably, researchers can combine the functionality of headnotes and the citation references to narrowly focus their case law research. This allows a researcher to know immediately

Figure 3 Lexis map.

Figure 4 Lexis discussion bar.

whether that point of law is still valid. (Remember that the warning yellow and red indicators for the cases will not specify which point of law has received negative treatment.) Researchers can even require that multiple headnotes appear within the text of a similar case. It is therefore possible to take a case that has thousands of citations and limit the results quickly and reliably to a manageable number. Using the above example for LexisAdvance, it is possible to look for all cases that have received both of the paths 'Labor and Employment > Leaves of Absences > Family and Medical Leaves > Remedies,' and 'Constitutional Law > Equal Protection > Gender & Sex.' This will result in a smaller number of cases, but the cases will be extremely similar.

Organizing Statutes with Legal Databases

Organizational Challenge of Statutes

Statutes are statements of positive law enacted by the legislature at the federal or state level. After the enactment of a federal statute, it is published chronologically in the Statutes at Large. However, Statutes at Large are not generally well indexed so researching them by topic is extremely difficult. In addition, the Statutes at Large are not updated to reflect changes to the text of a law. Laws are therefore divided and organized by subject matter in the United States Code ('USC'). Each volume of the USC covers its own subject matter and these topics are further subdivided into chapters, subchapters, and sections. There are two unofficial annotated versions of the Code: Lexis' United States Code Service ('USCS') and Westlaw's United States Code Annotated ('USCA'). If there were to be a discrepancy in the text of a statute, the language in the USCS would control because it mirrors the language published in the Statutes at Large. West, on the other hand, takes language from the USC. These statutory publications provide more information than the text of the law. The additional information contained in the unofficial versions is crucial to understanding how statutes have changed over time, how statutes interact with other statutes, and how statutes have been interpreted by various courts.

Search Capabilities on LexisAdvance and WestlawNext

When looking for a section of the code, both LexisAdvance and WestlawNext have smart search capabilities. LexisAdvance has a word wheel that brings a researcher into the correct act even if he or she only has a portion of the act name. For example,

typing 'medical leave' will suggest the term 'family and medical leave' and the researcher can quickly retrieve the 'Family and Medical Leave Act of 1993.'

As in print, one can browse the table of contents to the USC or to one of the annotated versions. To access this feature on LexisAdvance, one needs to click the 'browse sources' link above the search bar. After typing 'United States Code Service,' an option for the table of contents will appear. One can search within the table of contents for specific keywords or browse the entire code for relevant sections.

The text of these commercial annotated codes is updated more frequently than the text of the official USC. The USC is purportedly published every 6 years, which means language in the print volume might have been amended, deleted, or struck down by a court. This problem requires print researchers to turn to something called pocket parts: annual publications that supplement the USC. With a subscription service such as LexisAdvance or WestlawNext, changes to the text of the laws are amended directly in the annotated codes. These databases provide links to previous versions of the text as well as the links to the public law which amended the language. The insertion of amendments after the official text enables one to see not only the most current official language, but also changes that have occurred to the text and when the changes occurred.

Annotations

Researchers also benefit greatly from the annotations to the code on these subscription databases. Annotations are helpful references to cases, law review articles, and encyclopedia topics. The annotations are not part of the law itself, but are added to increase understanding of how the law is applied. Annotations group and classify related cases by subject matter. Someone looking at the cases citing to the 'Leave Requirement' section of the Family and Medical Leave Act will be able to identify cases dealing only with the 'expiration' element of the section's language. It is the editorial prerogative of the subscription databases to determine which cases are referenced in the annotations; therefore some annotations might appear in the USCS that do not appear in the USCA.

Shepardize and KeyCite Functions for Statutes

One can also use the Shepardize or KeyCite functions within statutes to create a comprehensive review of cases that have cited a particular statute. Many of the case law citatory filters, such as time and jurisdiction, are available for statutes. On WestlawNext, the 'citing references' filter allows the user to limit by notes of decision. This results in finding cases that have cited the statute, as well as providing the user access to standardized terminology. The standardized terminology in this filter provides users with more accurate results than they could receive by using a keyword search, because editors use the controlled vocabulary to place categorize all similar cases.

Platforms Providing Legislative History

As stated earlier, LexisAdvance and others publish the official text of statutes and provide information on amendments to the text, demonstrating how the text has changed over time. In some instances, one might need to identify why the changes occurred. The process by which one traces a law's development from the time it was a bill is known as legislative history. Students and practitioners can glean important information from changes that occurred in the bill's language, as well as the rationale issued in reports by committees that either endorsed or failed to endorse the bill. There are many important steps in conducting a legislative history, and subscription databases make the process more seamless than print resources. Importantly, many statutes already have compiled legislative histories available, which remove the legwork of tracking down various historical documents.

Conducting legislative history research can be a challenging endeavor when statutes do not already have a compiled legislative history, and there are too many steps to the legislative process to cover in this article. Anyone doing significant research into the legislative history of a statute should consult the commercial database ProQuest Congressional, which provides users with the most comprehensive set of legislative materials. ProQuest Congressional offers full-text congressional publications, including bills and resolutions, as well as both published and unpublished hearings. ProQuest also offers a service called Legislative Insight, which is a federal legislative history service that provides digital compilations of congressional publications leading to US public laws.

Dockets

Dockets are records of court proceedings for individual cases. Most users rely on dockets to research information contained in trials, which may last many years and involve many pleadings and rulings. Many researchers access dockets to find motions, transcripts of a testimony, exhibits, and jury instructions, among other court filings. The primary difficulty in accessing docket information is that dockets vary from jurisdiction to jurisdiction in the type of information recorded and in their availability to the public. Some jurisdictions might place all publicly available information online with open access, while other jurisdictions might require a visit to the courthouse. State court dockets are especially challenging to locate.

At the federal trial court level, the US government has created Public Access to Court Electronic Records (PACER). PACER charges users for each page viewed, so researchers often first try to conduct searches using one of the other databases referenced in this article. LexisAdvance, WestlawNext, and Bloomberg have incorporated PACER results into their own services with dedicated dockets tab. PACER results have their own limitations, and ultimately a trip to a courthouse might be necessary to locate the specific materials that are necessary for research. Most of the commercial vendors will send a runner to a courthouse to retrieve the docket information, for a fee.

Secondary Sources

Law Reviews

Researchers in the United States often consult secondary sources before beginning their legal research (Lihosit, 2009). Secondary

sources, including law reviews, treatises, and encyclopedias, provide critical background information on legal topics and can illuminate a field of law. Secondary sources are not binding authority, but they can sometimes be persuasive to a court. One particularly helpful feature is that they direct readers toward the most relevant cases and statutes. This is especially true of law review articles, which are extensively footnoted.

Academics contribute to the legal field by writing law review articles. Law review articles are one of the places students and practitioners turn to when researching a body of law for the first time, and a strong collection of law reviews are crucial for any library. Every law school has a flagship law review (otherwise known as a law journal) and most schools have secondary journals as well. These law reviews are traditionally edited by a group of students, who choose the content after reviewing submissions.

The legal databases have strong collections of law reviews, although coverage varies by publication. On LexisAdvance, law review articles will appear as a tabulated result under the 'Second' tab after running a keyword search. A keyword search might populate hundreds of thousands of hits, which make filters necessary to focus the results. One useful filter is the 'search within results' box, which narrows the results by introducing another word or set of words. LexisAdvance also provides a 'keyword' box, which suggests a list of potential terms that might be relevant to the search.

The Shepardize function on LexisAdvance works for law reviews as well, enabling users to parse out whether and where the article has been cited by various bodies, including courts and other law reviews. Contentious or influential law review articles will have many articles citing to them, which may indicate a reader should be familiar with the article. This is something one could not easily determine without a legal database such as LexisAdvance or WestlawNext. Google Scholar, for example, provides access to many law review articles but does not provide this additional signal.

As discussed earlier, one can find many articles from law reviews on both LexisAdvance and WestlawNext. These databases have certain limitations in both the breadth and depth of their collections. They also have limitations in their search functions. Because of these limitations, law schools in the United States will subscribe to a number of databases, including Hein and JSTOR, which provide access to additional journals. These full-text periodicals databases contain the actual text of the article in addition to descriptive information. They facilitate browsing and they may also provide enhanced search capabilities to allow for complex searches. Databases such as Hein and JSTOR also usually provide access to scanned pdf versions of the original print periodical, which make them useful for researchers concerned about accuracy. Finally, since many academics are interested in interdisciplinary research, coverage of legal databases is insufficient for their needs. For this reason, universities will subscribe to a host of other databases that provide access to journals in fields ranging from computer science to ethnic studies.

Periodical Indexes

Law schools also subscribe to periodical indexes, which are bibliographic databases that cite articles from a range of publications. These indexes do not always provide direct access to the articles themselves; instead they provide information that makes locating articles easier than locating articles using keyword searches. The indexes contain basic information from the articles as well as subject terms. Indexers assign subject terms to describe the contents of the articles. Articles assigned the same subject term are then cross-referenced to each other, which removes the problems associated with keyword searching (e.g., a keyword search for penitentiary will not retrieve results that use the word jail) and provides more precise results. If one searches for articles on 'self-incrimination' as a subject term, for example, the articles are likely to be narrowly focused on this topic. If one searches 'self-incrimination' as a keyword, on the other hand, results will simply contain the term anywhere in the article's full text. The second benefit of periodical indexes is that they cite to many more articles than are available on any one platform. This prevents the user from having to duplicate searches on different databases.

The two primary legal periodical indexes in the United States are LegalTrac and Index to Legal Periodicals. LegalTrac provides indexing for more than 1400 titles, including major law reviews, legal newspapers, bar association journals, and international legal journals. LegalTrac also contains law-related articles from over 1000 additional business and general interest publications. The Index to Legal Periodicals cites articles from more than 615 legal periodicals. LegalTrac only cites to articles dating back to 1980, whereas the Index to Legal Periodicals includes a Retrospective that cumulates citations from print editions of the Index to Legal Periodicals published between 1918 and 1981. There is also a print version of Index to Legal Periodicals, which goes back to 1908. The vast majority of these publications will not appear on LexisAdvance or WestlawNext.

However, scores of additional secondary materials can be found on LexisAdvance and WestlawNext. Both are particularly rich in treatises, which are books or multivolume sets devoted to particular legal subjects. Many treatises are highly regarded by courts, and courts will cite to treatises in their opinions, particularly when there is no controlling authority or when there are legal issues that have been resolved differently in varying jurisdictions. Courts cite to treatises in far greater numbers than other secondary sources (Merritt and Putnam, 1995). As with most secondary sources, however, the primary function is to illuminate the law for researchers. LexisAdvance and WestlawNext also provide access to American Law Reports, which are articles that provide background and citations to interesting or contentious legal issues; and Restatements, which are distilled summaries of common law principles.

While many secondary sources are published in print, LexisAdvance and WestlawNext provide greater access points to these resources, which can be found by title or keyword search. Perhaps most helpfully, LexisAdvance and WestlawNext often include links to secondary sources after the text of a statute or in the citation references to cases.

Conclusion

Lexis and Westlaw both offer products that make legal research significantly easier and more accurate. Attempting to conduct

serious legal research in this era without the assistance of one of the aforementioned legal databases would be a challenging endeavor. The utility of these products' digests and citation functions as a way to locate similar legal issues cannot be underemphasized. These databases provide access to statutes and legislative history, dockets, and provide a depth of secondary materials that illuminate the law and make conducting legal research significantly easier. While the article focused on benefits, it did not shy away from the handful of instances where LexisAdvance and WestlawNext do not provide adequate coverage for conducting legal research.

Although lawyers and practitioners might only have access to certain databases, the majority of the databases discussed in this article are available to all students enrolled in courses in US law schools. As a result, one can expect a newly graduated US attorney to have experience researching legal issues using more than one database. One downside to the procedure of giving every law student direct access to these databases is that students have unique user accounts. This means there is no institutional access despite the fact that non-law students and academics occasionally need to perform legal research. While non-law students and academics cannot access LexisAdvance or WestlawNext, Lexis and Westlaw both provide an academic platform for universities. However, many of the features described in the preceding pages will not be available to users on these academic platforms.

Abstract

Linguistic Databases include highly structured paradigms of information about language, such as is found in dictionaries, as well as collections of actual speech and writing. Such collections may include metadata describing how the data were produced or collected and annotation that adds analytic or educational value to the data, for example, transcriptions or translations. In the digital age, linguistic databases are critical components of language research, education, and technology development. As in other empirical sciences, data centers have arisen to address research community needs by creating, distributing, and archiving linguistic databases.

Definition, Examples, and Types

Definition

Linguistic Database is a broad term referring to a set of structured data related to language and, for our purposes, implemented on a computer. The term includes electronic dictionaries and similar databases, as well as the wide range of *corpora* described throughout this article.

Examples

Before defining additional terms it may be useful to give some examples. One of the earliest linguistic corpora is the *Brown Corpus*, created in 1961 from a collection of some 500 text samples totaling more than a million words of American English in 15 categories of writing such as news reports, editorials, book reviews, religious tracts, memoirs periodicals, government documents, technical papers, and fiction. Another example is the *TIMIT* corpus containing recordings of 630 Americans from different dialect regions each reading 10 sentences. The sentences were designed to contain many of the sounds of American English, including some that distinguish different American dialects. For example, all contributors uttered the sentence: "She kept your dark suit in greasy wash water all year," where the absence of the final 'r' in 'dark,' the substitution of 'z' for 's' in 'greasy,' the intrusion of an 'r' in 'wash' and the first vowel of 'water' are characteristic of some dialects. *TIMIT* also includes time stamps showing when in the recording, each word and sound was uttered. This allows researchers to quickly isolate and analyze different occurrences of individual words or sounds as uttered by a single speaker or multiple speakers. The *Penn Treebank* (Marcus et al., 1993) contains more than a million words of news text and conversation marked to show the grammatical structure of each sentence. *WordNet* (Fellbaum, 1998) organizes words into clusters of similar meaning, like a thesaurus, but also creates links among words through other relations, for example, when one word expresses a more specific concept than another (e.g., a cot is a kind of bed), or when one word expresses a part of another (e.g., a mattress is a part of a bed). Created originally for English, there are now WordNets in dozens of languages.

Users of such databases include linguists, or indeed any researcher whose work involves language, language teachers, and developers of human language technologies such as online translation systems, and voice command and response systems now appearing on smart phones.

Types

There are perhaps two main ways of organizing Linguistic Databases. Some contain systematic arrangements of *classes* of related forms and might be labeled *paradigmatic*. Tables of verb conjugations are classic examples of paradigms.

	Singular	*Plural*
First Person	I am	We are
Second Person	You are	You are
Third Person	He, she, it is	They are

However, electronic dictionaries also belong to this type when they contain systematic lists of forms with grammatical and semantic information about each. The second database type is organized around *sequences* of forms that occurred in actual speech or text. One might label this type *syntagmatic*, though the term is not widespread. More commonly, instances of this second type are called *corpora*.

Electronic Dictionaries

Types of Electronic Dictionaries

Electronic dictionaries are the most common and obvious examples of paradigmatic linguistic databases with thousands of instances online. The user experiences them as Web sites or software applications that permit searching and browsing *lexical* information; that is, information about the words of a language. However, behind that interaction is typically a database that contains many, highly structured lexical entries. Each entry will include a *headword*, the form under which information is gathered, and one or more components, e.g., parts of speech, definitions, glosses into other languages, pronunciations, usage notes, related words, time epochs, and genres in which the word appears, example sentences, and frequency counts. Electronic dictionaries may also include multimedia components, such as images that illustrate word meaning, and audio files of native speakers uttering the words.

Headwords and Organization

In Modern English dictionaries, the headword is typically a *citation form*, such as the first person singular of nouns and the infinitive form of verbs. Thus, users may be forced to find the definition of the word *geese* via the entry for *goose* and *broken* via *break*. Entries are also typically ordered alphabetically. However, other approaches are possible. Some older English dictionaries organize entries by meaning, and even modern dictionaries of Arabic may organize entries by root. They gather forms with shared histories and similar meaning or structure, as opposed to those with similar spelling. Electronic dictionaries frequently improve upon the utility of paper dictionaries, whatever their organizing principles, by allowing the user to search the full text as well as the headwords, and by including links to related forms. Finally for languages whose *morphology*, or system of word formation rules, is complex, electronic dictionaries may include a *morphological analyzer* or *stemmer*, a software component designed in this case to identify the probable headword for a given word. Thus a morphological analyzer for French might indicate that the words *mangeons (eat* as in *nous mangeons = we eat)* should be looked up as *manger* (to eat) and even that the word *suis (am* as in *je suis = I am)* should be looked up as *être* (to be).

The electronic dictionaries described so far are digital extensions of traditional paper dictionaries, intended as reference or for learners. Other types exist. *Pronouncing Lexicons*, support work in speech recognition and typically contain entries for all *surface* forms appearing in a corpus along with their pronunciations and frequencies. *Translation Lexicons* may also contain entries for words appearing in a corpus with one or more translations into other languages.

Challenges

Creators of electronic dictionaries face most of the challenges of traditional paper dictionaries plus a few others related to formatting and presentation. Until recently dictionary creators were forced to develop their own methods for storing databases on computers, accepting users' searches and presenting results. Within the past decade, proposals have emerged from different research communities for standards to structure digital dictionaries and permit data exchange. These include the international standard, Lexical Markup Framework, and the Lexicon Interchange Format.

One concern that challenged paper dictionaries publishers, but is effectively absent from their electronic implementations, is space. Publishers of paper dictionaries had to consider the costs and logistical issues associated with the size of dictionaries. However, for electronic dictionaries, space is effectively unlimited. Even a very large dictionary with, say, 100 000 entries plus pictures and sound files demonstrating how to pronounce each word would consume much less storage than a single HD movie today.

Corpora

Corpus (plural corpora), from the Latin for 'body,' refers not only to human bodies and certain bodily structures but also, for at least the past three centuries, to a set of texts collected under some organizing principle. One speaks of the corpus of works by a single author or about a specific subject. More recently the term has also come to mean a collection of texts or speeches used to study language. Here we define corpus as *any body of digital recordings of linguistic behavior developed for a specific, language-related purpose*.

Corpus Components

The form and content of corpora vary with intended uses but generally include: data, metadata, and annotation. The data, sometimes called *raw data*, are the plain recordings of linguistic behavior as audio, text or video files containing spoken, written, or signed language. Some practitioners resist the notion of 'raw' data claiming that any selection of data already encodes decisions about the phenomena to be studied. *Metadata* is information about the data, typically in the form of tables that enumerate various characteristics: the speakers, their demographics, and the circumstances under which recordings were made, etc. *Annotation* refers to the application of human judgment to add value to a corpus, e.g., the transcription of speech, translation into another language, or grammatical analysis. Annotation may involve direct human effort or may be computer-mediated when a computer algorithm annotates data which are subsequently confirmed or corrected by a human. It is worth noting that the algorithm may have also depended upon prior human annotation in such cases.

Users may also categorize corpora by the types of data and annotation they contain, e.g., speech, text, or translation corpora. However, corpora are also categorized by their intended uses.

Uses

Since corpora are developed for specific purposes, before discussing their creation and distribution it may be helpful to enumerate some uses. Language curriculum developers build corpora in order to extract usage and frequency information about words and grammatical structures; they employ this information to decide what aspects of language to introduce and in which order. Dictionary builders use similar information but also examine words in context to identify the multiple *senses* in which they are used. The word *bank*, e.g., may refer to the containing edge of a river or the financial institution. Linguists develop corpora to help document endangered languages and describe the current state of well-established languages that nonetheless change over time. Currently, the largest sources of linguistic data are language technology developer communities that recognize the importance of large, appropriately annotated corpora in their system building efforts. These communities are responsible for thousands of databases containing tens of thousands of hours of audio, billions of words of text, and hundreds of millions of annotation decisions.

Linguistic Databases perform a critical role in both the building and evaluation of human language technologies. A dominant paradigm in modern technology development exploits advances in *machine learning*, a probabilistic approach, in which computers learn to perform a task given enough examples of that same task having been performed on comparable data. For example, a French-to-English machine

translation system may learn from *training data* containing many examples of French documents with appropriate translations into English. Machine learning has led to advances in many language technologies: search engines, online translation services, and smart phone apps that respond to voice command and provide information using spoken natural language. Machine learning approaches also have the advantages that their performance tends to improve as they are given more and better data. Porting them to work on a new language ideally requires only supplying them with appropriate Linguistic Databases in that language.

Evaluating technologies for performance and usefulness also relies on Linguistic Databases. The common approach in human language technologies, as practiced in the evaluation programs administered by the U.S. National Institute for Standards and Technology, is to develop *test data*, new linguistic databases that represent the goal that the technology should achieve. For example, in the French-English translation system, the test set would be a new linguistic database, carefully constructed via human effort, never before seen by the system, containing appropriately selected French documents and their translations into English. During the technology evaluation, an existing system is given the French text and required to produce the translations into English. Those system translations are then compared to the human *gold standard* translations and the differences are scored according to user needs. Some uses may require that the translations contain all of the information in the original. Others may require that sentences in the output are perfectly grammatical. Still others may be able to tolerate some errors but require faster processing.

A few of the many technologies that rely heavily on linguistic databases are

- *Language Identification*: identifies the language(s) of a sample of text or speech.
- *Speaker Recognition*: indicates whether two or more recordings were produced by the same speaker.
- *Speech Recognition* (*Speech-to-Text*): transcribes spoken language indicating each word uttered and typically its speaker.
- *Dialogue Systems*: interact with humans via written or spoken language to accomplish a specific task.
- *Speech Synthesis* (*Text-to-Speech*): produces speech corresponding to input text.
- *Information Retrieval*: identifies documents relevant to a query.
- *Information Extraction*: identifies and categorizes mentions of persons, places, organizations, etc., as well as their activities and the relationships among them.
- *Question Answering*: accepts natural language questions and provides information or complete answers.
- *Summarization*: produces headlines or summaries of various lengths from one or more texts.
- *Machine Translation*: translates a document from one language into another.

Each of these uses requires different types of linguistic databases. For example, language identification from speech requires speech samples in the target languages and some nontarget languages with an indication, for each, of the language spoken. To assure that the technology is truly general, not biased toward a set of speakers, each sample should have only one speaker and each speaker should contribute very few samples. In contrast, speaker recognition requires multiple recordings from each of multiple speakers under different conditions that might include recording in person versus via telephone and speaking casually versus reading a text.

Data Sources

The recordings of linguistic performance that form the data component of corpora come from many sources and fit into four gross categories: text, audio, graphic, and video.

News text, typically acquired in digital form from newswire services or news Web sites, is an important source of well-edited, standard language addressing a broad range of topics, thus providing good coverage of the language's vocabulary. News text is intrinsically interesting and available in great quantities on an ongoing basis from a relatively small number of sources compared with collecting text from individual contributors. Research on specific linguistic genres may rely on corpora built instead from scientific journals or trade magazines or legal or financial documents. Recent work on computer- and phone-mediated textual interactions has required corpora of Web text, newsgroups and other discussion forums, blogs, microblogs, e-mail, chat, and messaging.

Researchers have collected spoken language from broadcast news and talk shows, podcasts, telephone conversations, lectures, interviews, meetings, read and prompted speech, task oriented speech, role playing activities, and Web video. Broadcast news probably makes up the greatest portion of publicly available audio data because it covers a wide range of topics and is available in large and rapidly growing volumes in many languages.

Work on optical character recognition, the creation of computer texts from printed texts, has built upon corpora of digital images of printed and, more recently, handwritten text, hybrid documents, such as printed forms completed by hand and text images appearing within video.

Video sources have typically been broadcast news. More recently, attention has shifted to user-contributed videos now commonplace on the Internet. Other video sources include recordings of interviews and group meetings, and, less frequently, movies and broadcasts that are not news.

Annotation Types

Annotations that researchers may apply to raw data are effectively unbounded; however, we can name some of the commonest. Pustejovsky and Stubbs (2012) treat many of the annotation issues raised here, and others, in more depth and from the perspective of developers of human language technologies.

Before data can be annotated, one must select an appropriate subset. However, data selection is best implemented as a preliminary annotation that marks individual items' appropriateness to subsequent annotation and retains such decisions for future use. To prepare, e.g., a corpus of French newswire with translations into English one might first annotate a large newswire collection for language and text characteristics and

use these annotations to remove documents that are not in French or that contain a predominance of numerical data or names. By retaining the annotations one avoids the duplication of effort that might occur if the corpus were subsequently expanded.

Audio data may be annotated, e.g., for perceived signal quality, language, dialect, speaker and, for broadcast speech, the name of the program recorded. Multiple recordings of the same event using different microphones, sometimes need to be time-aligned so that a researcher may search for words uttered in one recording and hear it in the other aligned recordings. Although there are systems that purport to maintain synchrony between recordings and techniques for recovering time alignment, human effort is still sometimes necessary.

Transcribing speech data makes it much easier to index and search. Transcripts are often *orthographic*, appearing in the writing system used by its native speakers. However, many of the world's languages have no standard writing system. In these cases, and also when the goal of the corpus is to support research in pronunciation, the transcripts may be *phonetic*, ideally using the International Phonetic Alphabet, though such rigor is still relatively uncommon. The time required to create an orthographic transcript of an hour of speech ranges from less than 10 to more than 70 h depending upon the method, expertise of the transcriptionist, degree of care taken, and how disfluent speech, nonspeech events (coughing) and things like acronyms (e.g., NASA, NAACP) are handled.

Researchers have annotated text, including transcripts of speech recordings, to mark the grammatical categories (e.g., nouns, verbs, etc.) and senses of words, to show the boundaries of grammatical structures, and to identify and classify mentions of entities (e.g., persons, organizations), relations, events, time, and locations.

Whole documents may be annotated to indicate their relevance to a search query, or they may be summarized or translated, though it is more useful when individual sentences, not whole documents, of original text are aligned with their translations.

Corpora supporting optical character recognition research have annotated digital pictures of pages to distinguish graphics from printed and handwritten text, to transcribe the text and indicate the order in which it should be read in documents with complex layout.

Metadata

Metadata typically deals with the humans who contribute language to the corpus, and the ways in which their contributions were recorded.

Metadata about talkers and writers tends to focus on personal characteristics that have been shown to covary with differences in language (Yaeger-Dror and Cieri, 2013). Sociolinguists have identified a wide range of these including the speakers' and listeners' sex, age, ethnicity, level of education and occupation, the places where they have lived, and their religious and political affiliations among many others. The recording situation can also impact the language collected. One can identify differences in the speech of a single individual across situations such as speaking to friends and family versus speaking to strangers, communicating in person versus at a distance, and reading versus lecturing. Finally, the speakers' attitudes toward the situation, including attitudes toward the listener and the topic of conversation, also impact the language recorded.

In addition, researchers frequently collect metadata about the method of collection, e.g., the microphones and recording devices used, their placement relative to the speaker, and the dimensions, shape, and characteristics of the recording space. This metadata, covering what are sometimes called *channel characteristics*, are especially important when speech is collected to support technology development.

The reader may have noticed a connection between metadata and annotation in that they are both about the data. The distinction is that *metadata* is the label applied to those characteristics of the contributors and situation that are planned or known in advance, while annotation requires some kind of judgment by humans reviewing the collected data. There are sometimes overlaps, e.g., when a researcher asks contributors to talk about a given topic (metadata) but subsequently reviews the conversation to determine whether they did so (annotation).

Distribution and Archiving

The distribution of a linguistic database to the intended audience in an appropriate form requires significant effort even after the database exists. Many of the issues that are important when the database is planned become critical once it is ready to be distributed.

Standards and Consistency

Appropriate distribution media depend upon data size and the technical capabilities of the intended audience. Current linguistic databases range in size from a few megabytes to nearly a terabyte depending upon whether the raw data is text, audio, image, or video. Appropriate file formats vary independently of media. There exist multiple competing formats for video (e.g., MP4, WMV), audio (WAV/RIFF, MP3), and even images and text, each with its own advantages and promoters. Any digital capture of a continuous signal such as speech or video unavoidably loses information; however, some *lossy* digital formats lose further information in their attempts to reduce file size. For speech where even uncompressed audio is small relative to current desktop storage capacity, it is relatively easy to advise against using lossy compression, such as MP3, for research purposes. However, for video where even a few dozen hours of uncompressed, high-resolution video could fill the average desktop computer, lossy MP4 video is much commoner. However, choosing formats for media files is the simplest of the format challenges. If the researcher has decided on a lossless compression the remaining formats are effectively equivalent and can be converted into each other with freely available tools. Of course conversion to a lossy format truly loses information that cannot be regained by conversion back to a lossless one.

Surprisingly, the situation is not as simple for text even though the adoption of the Unicode Standard for encoding

text has greatly simplified matters. Unicode assigns unique and consistent representations to the characters of the world's writing systems. Before Unicode, creators of electronic texts in languages for which there was not already a standard keyboard and character set were forced to invent their own representations for each new character. Consider the case of someone building a corpus of French, a language that includes *diacritic* marks over some vowels to encode differences in pronunciation, word origin, and meaning. French *mange* means *eats* (*il mange = he eats*) while *mangé* means *eaten* (*il a mangé = he has eaten*). Absent a standard to encode the character *é*, typists invented alternatives such as *e′*, *′e*, *E*, and just plain *e*, ignoring the difference. The lack of standards created inconsistency across and frequently within sources. Even after the introduction of character sets that address this problem for several Western European languages, the inconsistency persisted because the proposed solutions were partial and platform-specific, and achieved insufficient acceptance among users. Unicode has ameliorated this problem to a great degree though there remain numerous writing systems that lack adequate support within applications that purport to be Unicode compliant. *Tifinaghe* is the traditional writing system of languages that outsiders have called Berber or Amazigh and that native speakers call Tamazight and sometimes write ⵜⴰⵎⴰⵣⵉⵖⵜ. Closely related varieties are spoken by more than 15 million people in North Africa, from Morocco in the west to Libya and parts of Egypt and as far south as Niger, Mali, Mauritania, and Burkina Faso. There are also immigrant communities in Western Europe. Although this language has Unicode support, the actual character images of Tifinaghe are not implemented within character sets delivered with most common operating systems. So, writers invent their own representations of Tifinaghe characters. Amazigh has also been written in the Roman and Perso-Arabic scripts and has lacked a standardized representation for many words even within those scripts. One who would compile a corpus of Amazigh must overcome the challenge of normalizing not only the three scripts used, but also the ways those scripts are represented on computer and even the ways a given word is spelled within any one of them. To make this clear, even using the Roman alphabet one can find the name of the language spelled as Tamazight, Tmazight, Tmzight, Tamazirt, and Tamazert, among others. This unwanted variation impedes efforts to build corpora and thus technologies for Amazigh, despite its official recognition in Morocco and Algeria.

There are also numerous competing approaches for encoding annotations, most of which do not enjoy the status of a *de facto* standard. Once the file formats are chosen the distributor must assure that the corpus does in fact conform consistently to those standards. This can be a daunting task with data sets that include, e.g., billions of words of text and millions of annotation decisions.

For databases distributed in fixed formats and media, growth in knowledge about the languages may create a desire to update the databases. On the other hand, if the database is not fixed but allowed to change then its value as a means of evaluating technology is diminished, since even a single system's performance would be unstable if the test set were unstable.

Discoverability

Once the data are in a distributable form, the next challenge is communicating its existence, characteristics, and advantages to potentially interested users, assuring that the database remains discoverable by others who may be interested in the future. The number of researchers interested in linguistic databases changes not only with each graduating class but also with the growing recognition that many fields benefit from language technology. Bird and Simons (2003) deal with discoverability and other issues related to language documentation, especially for endangered languages.

Legal and Regulatory Issues

Distributors of linguistic databases must also face a number of legal and regulatory issues. Within the United States before collecting data directly from humans, even just speech or handwriting samples, one must develop a protocol to assure the protection of subjects and submit it for consideration by an Institutional Review Board regulated by the Federal government. Within most collections of linguistic data, the principal concern is that humans give their informed consent, and that they remain anonymous within the resulting data. However, one can easily imagine data collections with serious health risks. For example, a car manufacturer might wish to develop a voice command and response system that would refuse to start the car's engine if it detected, just by listening to some speech, that the driver were under the influence of alcohol. The data collection necessary to support such a development would presumably include many speakers contributing recordings of voice commands issued while both sober and intoxicated. The administration of the alcohol to subjects would indeed raise significant concerns for their well-being that would need to be addressed under very careful controls. Schiel et al. (2012) describe such a data collection conducted in Germany.

If the raw data in a linguistic database is instead collected from existing sources such as broadcasts, news text, published books, or user-contributed videos then, at least in the United States, a different set of legal constraints come into play. Copyright law gives the creators of such sources the sole right to copy, transfer, broadcast, and commercially exploit their products. This law is designed to encourage innovation by giving content creators the opportunity to be compensated for their efforts. However, the fair use exception to copyright law loosely defines situations in which someone is able to copy another's content, e.g., to build upon it or parody it. Determining which uses are consistent with copyright keeps many lawyers occupied. Complicating matters, laws and regulations differ from country to country and even where international treaties exist to deal with this problem they have not been endorsed universally or enforced consistently.

Reuse

Although we have only touched on a subset of distribution issues, we only have space to discuss one more briefly. Although corpora are developed for a specific purpose, the scarcity of linguistic databases relative to the demand for them

means that many corpora are reused in ways their developers never imagined (Graff and Bird, 2000). Knowing that such reuse occurs, corpus developers need to address quality issues throughout their data and follow best practices beyond those relevant to the initial use of data. Reuse also leads to the development of networks of corpora joined by their reliance on common data and their practice of adding annotation to existing corpora.

Data Centers

Modern desktop computing, storage and networking capabilities allow even individuals and small groups of researchers to create and distribute small-scale linguistic databases. However, developing larger scale databases, and addressing the myriad of technical, managerial, legal, and regulatory issues, as well as attending to challenges of long-term distribution, curation, and archiving, requires specialized equipment and skills. In the early 1990s, human language technology research communities recognized the need for an organization to specialize in this type of distribution, and founded the Linguistic Data Consortium (LDC). During its 22 years of operation the LDC has grown from a distributor and archive of linguistic databases to an organization that collects, creates, and annotates linguistic databases (creating hardware and software systems to assist in those activities). It also coordinates and consults on such activities internationally. Over the past decades other data centers have arisen and followed similar trajectories, such as the European Language Resource Association and the Linguistic Data Consortium for Indian Languages. Although individual researchers, research groups, and commercial organizations still create and distribute linguistic databases, these data centers account for the great proportion of all databases by title and volume and many database creators tend to deposit their work with data centers over time. The reader can visit the sites footnoted for each center to find catalogs totaling thousands of databases.

Abstract

In the social and behavioral sciences, the term 'database' refers to collections or aggregations of data sets that can be accessed through a unified repository or archive. Databases often involve data sets that vary over time (e.g., longitudinal data) or space (e.g., cross-national data). Since the 1960s, availability of and access to large databases have increased significantly, spurred by the development of archives across the world willing to store and curate data. As such, an increasing amount of scholarship has been accomplished using preexisting databases. This article also discusses different types of databases within the social and behavioral sciences, and provides considerations for existing challenges and new developments.

A database is any organized collection of information and its supporting structures. Within the social and behavioral sciences, databases tend to refer to collections or aggregations of data sets which can be accessed through a unified repository or data archive. Data sets comprising databases can consist of data (or information) collected at any level of analysis, from the individual (micro) to the organization (meso) to nation-state or country (macro). Indeed databases are often structured to introduce variation at multiple levels of analysis. For example, longitudinal studies, like the Panel Study of Income Dynamics (PSID), may connect changes in social mobility to changes in policy. Cross-national databases, like the European Social Survey (ESS), allow scholars to investigate relationships between country-level and individual-level variables. More broadly, databases frequently focus on aggregating data sets over time and/or space to allow for the exploration of fundamental social science questions, for example, change (or persistence) of social processes, establishing strong institutions, or the impact of macro-level processes or institutions on meso- or micro-actors. As many databases are made available for secondary analysis, or analysis by scholars other than the primary investigators with reference to questions not applicable or of interest at the time of collection, they also provide a repository of already collected data for social scientists to explore either before or in lieu of further data collection. The data archive at the Interuniversity Consortium for Social and Political Research (ICPSR) at the University of Michigan, for example, currently maintains more than 500 000 social science data files.

Databases as a Modern Phenomenon

Although databases are presently seen as central to much of social and behavioral science, the prominence and accessibility of databases are a truly modern phenomenon. Although instances of large-scale data collection (at both micro- and macro-levels) have been recorded dating back to Ancient Greece (Missiakoulis, 2010), databases, and especially those composed of individual-level social and political attitudes, values, and behaviors, are a quite recent phenomenon. Most accounts begin with the rise in importance of social scientists during and following World War II, due to increased government employment of social scientists (Almond, 1996). For example, Stouffer's interviews of more than half a million soldiers for his series *The American Soldier* led to new methodological developments with respect to measuring social attitudes as well as significant revisions to military policy (Stouffer et al., 1949). Around this same time, the Survey Research Center (SRC) at the University of Michigan garnered increased attention for successfully predicting the defeat of Dewey by Truman in the 1948 presidential election. As major pollsters, including Roper-Gallup, had reported a victory by Dewey, the prescient anomaly of the SRC's 662 respondents was enough for the Social Science Research Council (SSRC) to launch an inquiry into the methodological discrepancies (Miller, 1994). The SSRC inquiry led to a grant for the Michigan SRC to conduct another survey of the 1952 presidential election – a continuation which led to the eventual founding of the American National Election Studies (ANES) under the auspices of National Science Foundation (NSF) funding in 1977.

Prior to this point, data collection had been a largely individual pursuit, and scholars generally kept collected data as proprietary, even when funding was public. In discussing the early years of data collection, Warren E. Miller described data as the "scientist's capital," noting further that "they weren't about to share" (Austin, 1982). Following the establishment of the ANES as the nation's premier election survey, however, the scholars behind the study began to look for a cost-effective, 'consortial' way to disseminate the data. In the early 1960s, Miller began approaching political science departments across the country asking them to support an institute at the University of Michigan which would be responsible for permanent dissemination and protection of the ANES studies; in exchange, departments would get access to the full series of data. Although at the time, such a model was largely unheard of, by late 1962 Miller had recruited 21 institutions to join the consortium. Around this same time, Miller wrote a letter to the current director of the University of Michigan's Institute for Social Research (ISR), Rensis Likert, noting that while the SRC had a strong history of collaborations with *individuals*, continual *institutional* collaborations were necessary to ensure the continued development of rigorous survey research and analysis

Figure 1 Number of publications per year using data ICPSR databases, 1965–2010.

(Miller, 1962). Miller announced the founding of the Inter-university Consortium on Political Research (ICPR) in a 1963 article in the American Behavioral Scientist, which also noted "over the past year, [ICPR] staff made available to Consortium participants analysis books and codebooks for ten Survey Research Center studies," and listed a number of additional data sets being 'processed,' including Almond and Verba's classic Five-Nation Study, Dahl's New Haven Community Study, and U.S. Census data from 1950 to 1960. At the end of 2013, the ICPSR – which added 'social' to its name in 1975 to reflect growing interest in the Consortium by sociologists – boasted membership from 700 academic institutions and research organizations globally and archives for more than 8500 studies, including nearly 7400 with unrestricted access for members.

Just prior to the founding of the ICPSR at the University of Michigan, the Zentralarchiv für Empirische Sozialforschung (ZA) was founded by the Faculty of Economics and Social Sciences of the University of Cologne, Germany. During the 1960s, one of the ZA's first directors, Erwin K. Scheuch, began to work with Warren Miller and Stein Rokkan to develop some of the earliest infrastructure for comparative research and globalized social science. The Eurobarometer Surveys, for example, were established in 1973 as a joint effort between ZA, ICPSR, and Swedish Data Centers. Both ZA and ICPSR also worked with scholars from other countries to cultivate cross-national and international data archives. The Historical Archive of the ICPSR, established in 1966 began collaborating with French historians in the early 1970s to digitize data from the French census, as well as other industrial, educational, and demographic statistics. In 1986, ZA joined with the Social Science Information Centre in Bonn and the Centre for Survey Research and Methodology in Mannheim to create the German Social Science Infrastructure Services (GESIS), Leibniz-Institute for the Social Sciences. GESIS now serves as the main data archive for several major German studies, including Die Allgemeine Bevölkerungsumfrage der Sozialwissenschaften (ALLBUS), the Eurobarometer, and European Values Survey, and also offers archiving services to scholars looking to preserve and disseminate their data.

Since these early foundings, archives for databases have been established in a number of countries, including a number of countries in Eastern Europe, Asia, and South America. The establishment of archives has been so widespread that several umbrella organizations overseeing data archives have also been established, for example, the Consortium of European Social Science Data Archives, which was established in 1976 to provide access to data across countries, languages, and repositories. (For a full list of data archives by continent and country, see http://www.cessda.net/related_resources/networks_other_archives.html.)

The trend toward databases (and archives), however, has not been entirely supply-side. Since the 1960s, there has been a distinct upward trend in the number of scholars using databases for projects and publications. Figure 1 shows the trend in annual publishing with data available through ICPSR, from 1965 (shortly after ICPSR's establishment) through 2010, as collected by the ICPSR Bibliography of Data-Related Literature, which contains more than 65 000 citations of published and unpublished works using data from the ICPSR archives. The left axis corresponds to the solid black line showing the rise in all publications for a given year using ICPSR data over the period. This line shows a trend of strong yearly growth, starting from the early 1980s and extending into the early 2000s, cresting at more than 2500 works yearly using ICPSR data. Although the plot shows a leveling off starting in the early 2000s in the annual number of papers using ICPSR data, counts still top 2000 articles a year.

A similar trend can be found solely among dissertations and theses, as noted by the gray-dashed line (and corresponding right axis) in Figure 1, in spite of a long-held view in many social and behavioral science fields that PhD candidates should be required to collect their own data (thus demonstrating an understanding of the full scope of the research process). Rather, since the 1980s an increasing number of dissertations and theses have been approved using secondary data. Indeed, an article from the American Psychological Association's *grad*-PSYCH magazine in 2010 quoted one professor as saying it was "a crying shame" for doctoral students to collect new data, given the amount of preexisting, unmined data available from archives like ICPSR (Price, 2010).

Mechanisms behind Change

Although a number of factors have contributed to the increased development, dissemination, and usage of databases, three

mechanisms in particular deserve mention: (1) changes in computing technology that allowed for data to be stored and disseminated at low cost; (2) the establishment of 'gold-standard' research standards that increased the cost of data collection and placed a premium on expertise; and (3) an increased ethos of data sharing, wherein funding providers expect data to be shared with other scholars and preserved in such a way as to provide long-term access to the data. Note that although we refer to these as 'mechanisms,' it is clear that their development may have been concomitant with the establishment and development of databases and archives.

Advances in Computing Technology

Given the fundamental necessity of storage and access for the maintenance and dissemination of databases, advances in computing technology have provided the backbone for increases in database availability and use. Since the 1960s, the cost of data storage has declined from thousands of dollars a megabyte to less than ten-thousandths of a *cent* per megabyte. This decline in storage cost, coupled with the rise of increasingly efficient storage technologies (e.g., magnetic tapes to disk to, most recently, cloud storage) made the possibility of storing large databases, covering multiple countries or many years, possible. The advent of the Internet, further, allowed for efficient and far-reaching dissemination, initially of smaller documents like codebooks, but more recently of full data sets. Scientists no longer have to wait for disks or documentation of data sent via mail; rather they can find and (often immediately) download data sets to their personal computing devices. ICPSR even hosts the Social Science Variables Database, which allows users to search its data holdings for certain variables and compare across multiple databases to find the one(s) that best fit their needs.

One consequence of these computing advances was that new data and documentation are increasingly *created* in electronic format, hastening (if not eliminating) the process of converting data into a shareable electronic format for dissemination. Another consequence, however, was the rediscovery, preservation, and dissemination of 'historical' data. U.S. Census data, for example, can now be accessed online dating back to the 1790s. In 2004, a consortium of universities banded together to create the Data Preservation Alliance for the Social Sciences, established entirely to ensure the preservation and archiving of social science data 'at risk of being lost.'

Establishment of 'Gold-Standard' Research

In his letter to Rensis Likert purporting the establishment of (what would become) the ICPSR, Warren E. Miller noted, "The sample survey is by nature a highly technical and extremely versatile research operation. It requires a formidable combination of specialized personnel, complex methodologies, and organizational apparatus" (Miller, 1962). This early realization that top-notch survey research was both difficult and resource intensive served as a major impetus for forming a consortium of universities. Pooling resources (both intellectual and financial) allowed for the best methods to be used, thus increasing the likelihood of producing the most accurate results. It also allowed for the development of a 'gold standard' for survey research, requiring complete geographical coverage, high response rates, precision sample estimates, and low levels of measurement error (Heath et al., 2005). And while advancements in the areas of coverage, response, and error minimization provided for better and more accurate science, they also had the knock-on effect of making survey data collection an even *more* technical and formidable task. For many scholars considering collecting their own data, the premium for originality, was (perhaps more than) canceled out by the cost of falling short of this gold standard. Scholars without access to the top methodologies and technologies would do better to use 'good' data collected by others than to risk collecting data that might not meet established standards.

This is not to say that all databases currently available meet such 'gold standards.' Indeed, Heath et al. (2005) show that many of the most well-used cross-national databases fall far short of meeting such standards for some, if not most, of the countries included. Other scholars have argued that, with regard to previously unstudied topics, geographic areas, or time periods, that subpar data are preferable to no data. As such, the premium for original data collection has not disappeared entirely; rather those data considered 'original' are simply rarer.

As databases have grown in size and methodological sophistication, they have also been increasingly designed for secondary data analysis, or analysis by scholars not responsible for the study design. For many large surveys, secondary analyses are expected and welcomed. Major longitudinal and cross-national studies, like the ESS, the Survey of Health, Ageing and Retirement in Europe, and the PSID offer training videos and sessions for new users, and conferences for researchers at disparate institutions to connect. Further to this same idea, since 2010, the General Social Survey (GSS) has allowed scholars to submit proposals to add questions to the core GSS battery. In some ways, the 'gold-standard' establishment has led to a bifurcation between those scholars who design surveys and focus publishing on questions of methodology and research design, and those who analyze surveys, with publication focused on broader and more substantive issues.

Increased Ethos of Data Sharing and Curating

In 2009, the journal *Nature* noted, "Research cannot flourish if data are not preserved and made accessible…a research project's success is measured not just by the publications it produces, but also by the data it makes available to the wider community" (145). Although the replication and confirmation of results have been considered an important pillar of the scientific paradigm at least since Kuhn (1970), social and behavioral scientists have generally been slow to make their data available. In many ways, original data are a quintessential public good; although the entirety of the field benefits from more data being made publicly accessible, each individual investigator must be willing to take on the 'cost' that goes in to making their data public. In this case, 'cost' is not only findings potentially lost to other scholars, but also the process of cleaning, documenting, and hosting the data in such a way that it can be accessed and analyzed by other scholars.

Recently, however, other institutions have set about trying to rebalance this equation, and to encourage scholars to share their data, either for purposes of secondary analysis or replication. Data archives, such as those discussed above, are

increasingly offering curation and archival services, reducing both the temporal and financial burden on investigators willing to share their data with others and also providing long-term safeguards for data preservation. More coercively, the major public social and behavioral science funding bodies in the U.S. – namely the NSF and the National Institutes of Health – in recent years have instituted a formal requirement that grant recipients or applicants establish plans for sharing and archiving data. Although these plans are not considered in the proposal review process, they nonetheless require investigators to explicate their intentions for 'managing' their data alongside other well-established ethics of, e.g., participant confidentiality. The UK's Economic and Social Research Council, the country's foremost funding body for social research, and the German Research Council have similarly established guidelines for investigators to discuss 'data management plans' in their proposals.

Recent years have also seen an increase in calls for availability of data for purposes of replication. Several major professional organizations, including the American Sociological Association, American Association of Public Opinion Research, and the American Psychological Association, have addressed issues of replicability in their guidelines for best practice, in all cases noting that scholars should be willing to make their data available for purposes of replication. An increasing number of journals in the social and behavioral sciences have also established policies of 'data availability,' ranging from authors including their data and replication files at submission (e.g., *Journal of Conflict Resolution*, *American Journal of Political Science*, *Political Analysis*) to simply 'expecting' that authors provide replication data and files 'upon request' (Gherghina and Katsanidou, 2013). These changes, alongside calls from well-known scholars like King et al. (1995), King (2006), and Freese (2007), seem to indicate a trend toward data sharing that is unlikely to reverse.

Classifying Databases

Continuing from Campbell (2001), most databases can be thought of as belonging to one of the following categories.

Cross-Sectional Micro-Level Demographic Surveys

Cross-sectional micro-level demographic surveys are typically collected and organized by government agencies as part of their efforts to enumerate their populations while also gathering information about their composition. In the United States, for example, government agencies like the U.S. Census Bureau gather information on the American population periodically by asking individuals basic questions about their households. These data are used for official purposes, such as the apportionment of seats in the legislature and the drawing of district boundaries, and also made available to the public for research purposes. In this sense, the data serve a dual purpose, both influencing official policy as well as increasing our knowledge of population trends through secondary analyses. The U.S. Census Bureau also collects data in important survey programs fielded regularly between census periods: the Current Population Survey (monthly) and the American Community Survey (annually). With respect to international or cross-national research, Census data often provide measures that can be easily understood or compared. The Integrated Public Use Microdata Series (IPUMS), maintained by the Minnesota Population Center, allows scholars access to 1% samples of U.S. Census data from 1850 onward, as well as harmonized Census data from 74 countries, covering more than 544 million people.

Macro-Level Social and Economic Data

Many countries also collect important macro-level data – generally, at the country or state level. For example, the U.S. Department of Agriculture Economic Research Service collects data about agricultural activity in the U.S. as well as data on the prices of important agricultural commodities. The Department of Homeland Security estimates the number of immigrants in the United States and collects the data in its *Yearbook of Immigration Statistics*. These data allow social and behavioral scientists to study large-scale, macro-level trends.

In Europe, many countries have statistical bureaus that collect data on their country's demographic and economic activities. For example, Germany's *Statistisches Bundesamt* (*Destatis*) is responsible for collecting, processing, and analyzing data on the German economy and society. At an even larger aggregate, the European Union's statistical office, Eurostat, collects social and economic statistics for both the EU as a whole and each constituent nation, providing a comprehensive database for study.

International organizations also compile important macro-level data from various countries and offer these data to the public. The World Bank and the International Monetary Fund, for example, provide extensive data on economic development and inequality for most countries. The United Nations Population Division collects data on the demography of UN member countries, including measures of mortality and fertility rates, population growth, and urbanity. The Organization for Economic Cooperation and Development also collects data on social and economic trends for its (largely developed) member countries.

Cross-Sectional Micro-Level Social Surveys

Other sources of cross-national data do not come from government agencies but rather from research programs aimed at documenting public opinions and behaviors across a range of countries. Such programs are typically organized and designed by academics with expertise in specific areas of the social and/or behavioral sciences. Collection of these cross-national data typically involves surveying a nationally representative sample of each country's (or nation's, as appropriate) population, oftentimes in multiple 'waves' over time. The International Social Survey Program (ISSP), for example, is an annual survey program that coordinates the thematic content and fielding of surveys across its member countries. The ISSP has included 53 nations since 1984, developing annual topics that are relevant to researchers in the social sciences and fielding topic-specific modules as 15-minute supplements to regular national surveys (e.g., the GSS in the U.S., or the British Social Attitudes Survey in Great Britain). ISSP surveys give

researchers data on the subjective attitudes and values of national publics with regard to important social, political, and economic issues. The World Values Survey (WVS) is another centrally coordinated cross-national survey project, designed to examine political and sociocultural change. Unlike the annual ISSP, the WVS produces 'waves' on approximately four-year time scales; this longer time scale allows the inclusion of lesser-developed countries not often included in other survey programs.

Nonacademic survey programs with cross-national coverage include the Gallup World Poll and the Pew Global Attitudes Project surveys. While these surveys are guided less by academic research agendas, they are fielded annually (and sometimes semiannually), providing especially up-to-date data on people's attitudes and beliefs from around the world. These programs release data to the public on a release schedule, typically following the release of their own prioritized reports and products.

Other survey programs forgo global coverage to focus on one particular region. The ESS, for instance, has conducted surveys across Europe every 2 years since 2001, exacting some of the highest methodological standards in the field. Other region-specific survey programs include the various 'Barometer' projects (e.g., Afrobarometer, AsiaBarometer, Latinobarómetro, Eurobarometer) and Vanderbilt University's Latin American Public Opinion Project.

Longitudinal Micro-Level Surveys

Distinct from the survey programs discussed above, project-based databases track the same population sample – or panel – over time, typically with the objective of addressing subject-specific research questions. Such panel databases have flourished in recent decades as education, health, and aging and the life course have become important areas of interest to researchers, policy analysts, and government officials. The National Longitudinal Study of Adolescent Health (Add Health), for example, provides data on the general health and well-being of American adolescents by tracking a nationally representative panel of teenagers in grades 7 through 12 into adulthood. The Add Health database has been groundbreaking not only for its design and coverage, but also because it contains data on both respondents' networks (including families, schools, peer groups, romantic relationships, and communities) as well as respondent biomarker data. As such, Add Health data allow investigators to explore the connections between social context and individual outcomes, as well as interactions between biology and the social world. Other longitudinal panel surveys include the National Educational Longitudinal Survey, the pioneering Wisconsin Longitudinal Survey started in 1957, and the PSID, ongoing since 1968.

Ongoing Challenges in Database Construction and Usage

Advances in data storage capabilities combined with the push to collect increasingly more economic, social, and demographic data have led to the establishment of a number of important databases made available by government offices, academic consortia, nongovernmental organizations, and private entities. While these databases offer increasing amounts of information and potential for investigation, these increasingly complex databases also pose a variety of challenges for scholars in the extraction, use, and analysis of data.

Much government data, for example, are often available only in raw formats, which prevent most researchers from easily extracting and using the data. Fortunately, third parties have made efforts to facilitate secondary analysis of government data by researchers. The previously mentioned IPUMS, for example, has collected data from the U.S. Census Bureau dating back to 1850. Prior attempts at providing samples of U.S. Census data for research purposes led to a confusing array of record layouts, coding schemes, and documentation. IPUMS standardizes these by assigning uniform codes and names across all samples and providing coherent documentation of the data. IPUMS also makes available Census samples from a broad array of countries, including the United Kingdom, France, and Switzerland as well as Mexico, Kenya, and Indonesia, with samples data dating back to 1960. To further encourage cross-national work with these data, for a number of measures IPUMS also provides data 'harmonization' – or the integration of data from heterogeneous sources – across countries. Although processes of harmonization may not be ideal for all research purposes, they can help researchers explore similarities and differences across databases that encompass important spatial and temporal variation.

Some government databases can also prove difficult to access. Register databases, for example, while extensive and comprehensive, are often protected by law to ensure individual residents' privacy. Statistical bureaus in many European countries limit register database access to researchers who provide evidence of their need and, thus, are not 'publicly' available in a broad sense. Concerns for respondent privacy also lead to restrictions on a number of survey databases. Often, such databases will offer a publicly available version of the data that exclude certain identifying variables, as well as a full, 'restricted-use' version that requires users to agree to protect confidentiality of respondents, not share data and/or access, and analyze the data only on certain computers.

Even when data are relatively easy to extract and use, there are challenges that arise in the analysis of data. With cross-national data in particular, researchers must determine whether the data available for a set of countries contain equivalent measures for the same concept – that is, whether the data are commensurable. Differences in how survey questions are translated or interpreted among different cultural or linguistic groups, for example, can lead to problems of comparability that even the most advanced of statistics cannot sort out. While those involved in survey planning and administration have become increasingly aware of issues related to the translation of survey instruments (Smith et al., 2011), studies continue to find that cultures using the same language exhibit higher levels of measurement equivalence than cultures using different languages (Davidov and De Beuckelaer, 2010). Issues of cross-national equivalence may persist even as survey products trend increasingly toward the established 'gold standard,' making the role of the analyst in analyzing cross-national data specific and important.

Increased reliance on databases may also raise questions about differences in status between those in the social and behavioral sciences who create and manage databases and those who use databases for secondary analysis. While secondary analysts spend much of their time testing hypotheses and writing up results, those who create and manage databases, in contrast, spend a great deal of their time ensuring that the data – in addition to being scientifically founded – are methodologically rigorous, representative, organized, documented, and accessible. This difference in focus brings about very different final products, which are in turn valued differently. Top-tier journals, for example, often put a premium on first passes at new data or advancement of methodological problems, while scholars retreading old ground (however rigorously) may have a harder time achieving publication. Further, with respect to funding bodies, monies available for the collection of new data far outstrip those available for secondary analyses. As such, and looking forward, we should be aware that disparities in values and resources may risk the creation of a two-tiered system within the social and behavioral sciences.

Big Data and the Future of Databases

The most recent developments in database construction and design reveal a focus on data that do not come from traditional sources such as government agencies, administrative registers, or survey programs. Rather, new sources of data include those produced by unknowing users of everyday technological products, including records kept by companies on the online activities and even physical locations of users. These new sources of data, collected by technology juggernauts such as Google, Twitter, and Facebook, have raised a number of new questions about privacy, consent, confidentiality, and accessibility, and will likely require social and behavioral scientists to consider and codify new ethical and logistical standards for the collection and analysis (or 'mining') of such data.

While improvements in technology have developed largely separate from scholarly data concerns, new opportunities for data collection and database construction nevertheless emerge. With the rise of social media technologies and the digitization of records come traces of raw data left behind by people living their everyday lives. Data from sites like Twitter, cell phone usage data, and digitized spending records compiled by banks and retail merchants all make up this type of data from daily life. Social and behavioral scientists have referred to these organic data as 'big data,' characterizing the scale on which the data are almost effortlessly and consistently produced (Boyd and Crawford, 2012).

Yet, the scale of these databases presents new challenges for scientists. For one, researchers are often not aware of the variety, nor familiar with the quality, of data contained in these records, making the extraction of useful data difficult. Further, the sheer amount and variation within the data found in these data sources prohibit treating them like even the most complex Census database, which tend to be limited and often standardized during any given period. There are also questions concerning the selection of such data as the research standard of representative sampling is difficult to implement and not always practical with such large-N data.

Furthermore, concerns about privacy have stirred controversy. Often, individuals 'producing' big data are not fully aware that they are leaving behind data as they engage with technology and applications. As technology becomes increasingly mobile and 'real time,' individuals are at risk of releasing data from many aspects of their daily lives, interactions, and locations. Such data may be collected by government agencies, private companies, as well as public users; further, modern legal standards pertaining to the expectation of privacy do not apply to noncontent data provided to online sites such as Twitter (Shickich, 2013). As such, big data occupy a legal space somewhere between the public and the private. It is yet to be determined whether the construction and use of such databases should require individuals' notice and/or consent.

Data Bases and Statistical Systems: Political Behavior and Elections

Rüdiger Schmitt-Beck, University of Mannheim, Mannheim, Germany

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The article reviews the global landscape of national and cross-national survey-based infrastructure programs of more or less regularly collecting data on political behavior and citizenship. Two developmental trajectories are distinguished. National election studies were strongly inspired by the American National Election Studies; their global proliferation eventually gave rise to cross-national programs like the Comparative Study of Electoral Systems. The Eurobarometer and the American General Social Survey spurred the development of replicative data collection programs on nonelectoral participation and citizenship. This development culminated in the creation of programs like the World Values Survey and the European Social Survey.

Given the institutional centrality of elections in representative democracies, it cannot come as a surprise that political scientists have always accorded them special attention. Electoral research was the earliest type of inquiry into political behavior to emerge; its pioneer studies date back a full century. Since the mid-twentieth century electoral research has developed into a highly integrated subdiscipline of international political science, and accumulated a massive, mainly survey-based data inventory of national, as well as more recently international, comparative election studies. Electoral research started out to answer two main questions: Who votes in an election, and why? If citizens take part in an election, which parties or candidates do they choose, and again, why? In recent decades, it moved beyond this voter-centric perspective and expanded its scope to broader analyses of elections and their functioning in processes of democratic representation and accountability. Research into other forms of political participation started in the 1960s and opened itself up to internationally comparative perspectives much earlier than electoral research. Comparative research into democratic citizenship more broadly was inaugurated in 1963 with Almond and Verba's famous 'Civic Culture' study. The first programs of replicative national and international representative population surveys on political participation and citizenship started in the 1970s. They developed into a second pillar of survey-based political science data infrastructures alongside electoral studies, with a broader focus than the latter. However, most of these programs did not exclusively cater to the data needs of students of political behavior. They are typically interdisciplinary in orientation, and politics is just one of several mostly sociological themes covered. The data infrastructure generated by these programs is not merely relevant for academic research into political behavior, which seeks to improve scholarly understanding of democracy. It also constitutes a valuable asset for the self-observation of democratic societies and their transformation over time, with powerful potential for enlightening policy makers, journalists, and concerned citizens alike. Its creation and continuous updating is thus an important contribution to the public good of democratic societies.

Data Infrastructures for Electoral Research

From its earliest beginnings, electoral research has defined itself as a quantitative, empirical social science and, as such, it has always been in need of reliable and valid data on citizens' electoral behavior. Qualitative approaches never gained any significance in electoral studies. The pioneer studies of the early to midtwentieth century found a useful source of electoral information in the data collected by statistical offices as part of their administrative duties. Landmark studies like André Siegfried's inquiry of French 'electoral geography' in the nineteenth century (published in 1913), Rudolf Heberle's 'political ecology' of National Socialism in Germany in the early 1930s, Herbert Tingsten's analysis of class voting at the 1932 Swedish election, or V.O. Key's 1955 study on the politics of the American South laid important intellectual and methodological foundations for the discipline by investigating how turnout and vote shares in nation states' territorial subunits, such as electoral districts or counties, covaried with global and aggregate attributes of the same units, ranging from geographic features to cultural and socioeconomic characteristics. However, although profoundly innovative at the time, the scientific scope of aggregate studies such as these was constricted by their inability to observe electoral behavior at the analytical level where it occurred – the microlevel of individual voters. Correlational studies of aggregate data are always vulnerable to the ecological fallacy – the risk of drawing erroneous inferences from aggregate to individual-level relationships. In recent years, statistical techniques have been developed to attenuate this problem, but the heyday of the aggregate approach to analyzing electoral behavior has long since passed. In the 1950s, a trend emerged in American electoral research, which quickly set a new standard in other democracies. Centered around a technique of collecting data on electoral behavior, the new trend became the canonical method of electoral research worldwide to the degree to which it was feasible in the respective countries. The cross-sectional large-N random sample survey, representative of the whole voting age population of a nation, was based on standardized questionnaires and conducted face-to-face. Compared to the data sources dominant during the pioneer era of electoral research, this new approach brought with it at least three major advantages: (1) measurement was located at the level of individual voters; (2) data collection was under the control of scientists themselves, so the core constructs of theories of electoral behavior could be optimally operationalized; and (3) the range of measurable explanatory factors expanded beyond the objective attributes recorded in official statistics to include

 http://dx.doi.org/10.1016/B978-0-08-097086-8.41075-5

also subjective phenomena like values, beliefs, and attitudes. These advantages were traded against a diminished validity with regard to the dependent variable, as research now relied on self-reports by survey respondents instead of records of actual voter behavior (although in the United States, at least for turnout validation is still possible using official voter records).

The new design quickly defined what in time came to be seen as the international 'gold standard' of electoral research. It crowded out not only studies based on aggregate data which retained some significance only in historical election studies but also its greatest competitor, the sociological perspective advocated by Paul Lazarsfeld and his colleagues at Columbia University. This approach conceived of voting as an activity of citizens embedded in, and responding to social groups, and demonstrated its utility during the 1940s in ingenious studies using local multiwave panel surveys. Nonetheless, for a number of reasons, the coming decades were dominated by the intellectual and methodological agenda of what came to be known as the Michigan school of electoral research.

During the 1948 US Presidential election, researchers of the Survey Research Center (SRC) of the University of Michigan led by Angus Campbell created what eventually became the longest uninterrupted series of election studies of the world and a blueprint for election studies worldwide. From 1977 onward, the US National Science Foundation (NSF) funded this project, now relabeled the American National Election Studies (ANES), as a 'national scientific resource'. While data had already been treated as a public good prior to this change, a new governance structure was now established that allowed the scientific community to participate in defining the research agenda. The new structure consists of Principal Investigators as study directors, a Board of Overseers as supervisory and review body, and various ad hoc committees. Project staff is funded to ensure the high methodological quality of data collection.

Regarding its content, the SRC/ANES series' intellectual point of departure is best described by the 'funnel of causality' proposed by its creators in their famous study of 'The American Voter' as a heuristic tool for understanding electoral behavior. It sees voters' psychological orientations as immediate antecedents of electoral choices, most notably beliefs and attitudes concerning issues and candidates, which are assumed to reflect the specific circumstances of particular elections, but also voters' stable partisan identities. Mediated by basic group identities and values, these party affinities can be ultimately traced back to historically rather distant structures of social and cultural conflict. Decades of scholarly debate have transformed, differentiated, and expanded this initial agenda, although the studies' theoretical and methodological focus on independent individuals as core units of electoral analysis remained unchanged over the years.

Despite having created a series of high-quality surveys spanning all presidential and many congressional elections of more than six decades, this extremely successful social science infrastructure program has been placed in jeopardy in recent years, as policy makers have proposed the exclusion of the ANES from the NSF funding remit. This is an ironic development, given that its basic philosophy and design had quickly after its inception turned into an attractive export item, setting in motion, a global proliferation of national election studies trying to emulate its core features: the high methodological standards and long-term continuity; openness to the scientific community with regard to input and output, that is, with regard to instrumentation and design as well as with regard to timely and unrestricted data access; clear and transparent structures of governance and accountability.

Sweden (1956), Germany (1961), the United Kingdom (1963), Norway (1965), and the Netherlands (1971) stand out as early adopters. Many of these new national election studies profited from direct involvement of the Michigan scholars. Today in many democracies, national election studies are conducted more or less regularly at the occasion of parliamentary and, where it applies, presidential elections. Besides the already mentioned countries, the Consortium of European Social Science Data Archives (CESSDA) guide to national election studies in Europe listed already in the mid-1990s studies from Austria, Belgium, Denmark, France, Hungary, Italy, Spain, and Switzerland (Hartmann and Oedegaard, 1997). Outside Europe, similar data collection programs were inaugurated in countries as diverse as Australia, Canada, India, Israel, Japan, New Zealand, and Taiwan. Several studies went even beyond the ANES model, for instance by placing special emphasis on interelection panels (UK) or by adding studies of media and parliamentarians (Sweden).

Despite their *de facto* regularity, these data collection efforts are usually less generously and often also more precariously funded than the American prototype. Only a small number of studies enjoy the security of institutionalization as national science infrastructures with stable funding. Several studies obtain funding by organizations equivalent to the NSF. However, it is often granted only on an ad hoc basis and has to be secured for each election anew. Sometimes funding also comes completely or partly from nonacademic sources, including public agencies like statistical offices, ministries, or parliaments, but also mass media or other private agencies. Securing uninterrupted series of national election studies is no small achievement under such circumstances, and in some countries, such as France, studies are only realized irregularly. Since many programs thus follow incremental trajectories rather than grand designs, data comparability over time is often less than optimal. The degree of openness to the scientific community varies as well. Most studies have subscribed to an ethos of institutionalized accountability to the profession, but some share their data only after an embargo period. Even less well developed are participatory instruments to provide the scientific community with significant influence on the studies' content.

While in recent decades, many countries have established more or less stable programs of national election studies; the field has also substantially expanded its scope in several ways. Traditionally, election studies tended to see individual voters and their attributes as the sole key to understanding elections. This voter-centric paradigm has increasingly given way to a broader perspective that seeks to understand elections as part of multilevel processes of democratic representation. This requires expanding the scope of data collection and analysis so as to refer not only to voters and their reasoning when making up their minds at the polls but also to the manifold interactions between voters, parties, candidates, and incumbents, with traditional and new media functioning as mediating agents. As voter behavior has become more individualized and volatile, election studies have also enriched their designs with

longitudinal components (from short-term panel and rolling cross-section campaign surveys to long-term panels and tracking polls over entire electoral cycles). Some studies also revive the discipline's seemingly outdated interest in aggregate data by combining such information with individual-level voter data for contextual analyses using multilevel modeling.

Another crucial development is the growing interest in internationally comparative studies. Electoral studies were slower at incorporating a comparative perspective than other fields of research into political behavior. National elections are in many respects idiosyncratic affairs (beginning with their dates), and studying them in an internationally comparative framework poses serious challenges in terms of theory, study design, and instrumentation. It seems, therefore, quite natural that the first large-scale comparative election study – the European Election Study (EES) 1979 – was not focused on national elections but on multinational elections to choose the members of a supranational political body: the European Parliament. Since then, EES data have been collected for each European election (partly in connection to Eurobarometer (EB) surveys; see below), although each wave had to face new challenges, especially in securing funds from a variety of sources (Schmitt, 2010). More, importantly, since beginning the EES has sought to move beyond sole reliance on voter surveys by conducting media and party manifesto content analyses, as well as surveys of political elites. During the 2009 European elections, these efforts culminated in a complex pilot study for the creation of an extensive European data infrastructure (Providing an Infrastructure for Research on Electoral Democracy in the European Union (PIREDEU)).

More recently, comparative electoral research also turned to national elections and the question how electoral behavior responds to variations in political systems' institutional architecture. Due to their common intellectual origins, many national election studies appear quite similar with regard to their core constructs, although country-specific measurement solutions were often implemented. Against this backdrop, heroic efforts were undertaken to realize the potential of existing data on European electoral behavior by harmonizing voter surveys from various countries' national election studies and combining them into a single data set. The 'European Voter' project (Thomassen, 2005) initiated this formidable task by merging and analyzing data from six countries over more than four decades (Denmark, Germany, Netherlands, Norway, Sweden and UK). A successor project – 'The True European Voter (TEV)' – began in 2009 with the mission to expand the range of countries to include the rest of Europe. At present, national election studies from 26 countries participate in this collaboration. While these programs aim at output harmonization of existing data, two other networks are building databases using election surveys specifically conducted for the purpose of international comparison. Since 1990, the Comparative National Elections Project (CNEP) has assembled a collection of 25 election studies conducted in 20 countries, ranging from the United States to Mozambique. Two elements are essential for the CNEP: an attempt to revive the neglected research agenda of the Columbia school, which placed an emphasis on institutions and practices of political intermediation (interpersonal communication, mass communication, campaign communication of parties, and other organizations), and a pronounced interest in the electoral politics of new democracies. Due to its focus on communication phenomena, this project has not only generated voter surveys but also media content analyses and data on voters' egocentric networks (Gunther et al., 2007).

The Comparative Study of Electoral Systems (CSESs) is more modest than the CNEP in one respect, which allows it to be more ambitious in several other respects (Klingemann, 2009). It does not require participant countries to run full-fledged election surveys for the sole purpose of integrating them into a cross-national database. It rather asks country collaborators to include a commonly agreed-upon question module of limited size in postelection surveys of their national election studies (and thus accepts variability in survey modes). This makes participation less costly, and as a consequence, the number of countries involved in the CSES is much larger (at present almost 60). Every 5 years, the CSES enters a new cycle of fielding survey modules on a particular theme in as many countries as possible. The first round of the project (1996–2001) focused on the impact of electoral institutions on citizens' political cognition and behavior and the nature of political and social cleavages and alignments, as well as the evaluation of democratic institution and processes, the second (2002–06) on aspects of political representation. The third round (2006–11) is interested in the meaningfulness of electoral choices and the currently running fourth wave (2011–16) has a special focus on electoral mobilization and political knowledge as well as distributional politics and social protection. An important feature of the CSES is that its integrated survey data sets are enriched with system-level data on electoral rules, regime characteristics, and district and overall election outcomes, inviting multilevel analysis. CSES data are treated as a public good. A Planning Committee of elected members is responsible for the program's strategic decisions. A Secretariat, cofunded by the University of Michigan's Center for Political Studies and GESIS – Leibniz Institute for the Social Sciences, takes care of day-to-day management and data work.

Data Infrastructures for Research into Political Participation and Citizenship

The global proliferation of survey-based political data infrastructures beyond electoral studies during the past four decades can be traced back to two crucial initiatives: the gradual implementation of the EB by the European Economic Community since 1962 and the creation of the American General Social Survey (GSS) in 1972. The EB has run biennially as a tool for regularly monitoring public opinion in all member states of the European Union (Reif and Inglehart, 1991) since 1973. About 1000 interviews are conducted in each country per round. The number of countries included in the EB has increased as EU membership has grown. Survey questions primarily cover perceptions and attitudes toward European integration but also more general political, cultural, and social orientations. In the late 1980s, an add-on program of 'Flash' surveys expanded the standard EB. In 1990, the Central and Eastern EB was launched, which would later become the Candidate Countries EB. Although funded and controlled by the European Commission, the EB has, to varying degrees,

been responsive to demands of the academic community. More importantly, the scientific community is granted open access to the data via data archives, which have become an indispensable asset of longitudinal and cross-national comparative research into Europeans' political beliefs, attitudes values, and participatory orientations. The five volumes of the 'Beliefs in Government' series edited by Kaase and Newton in 1995 best exemplify this.

The Global Barometer (GB) is a program that took inspiration from the EB but is independently conducted. In fact, it consists of five successively established but not very tightly integrated, regional programs that include about 75 countries on three continents: the New Europe Barometer (1991) created in a number of recently democratized Central and Eastern European countries, the Latinobarometer (1995), the Afrobarometer (1999), the Asian Barometer (2001), and the Arab Barometer (2005). The GB's thematic focus on orientations toward democracy questions each respective country's social, economic, and political conditions. At the same time, the program is also supposed to assist in improving survey research capacities in countries where such industries are underdeveloped. The various regional programs have achieved different degrees of regularity in data collection, as well as data comparability across time and countries. More importantly, in contrast to most other programs discussed here, not all GB data are available to the scientific public.

Another indirect outgrowth of the EB, the European Values Study (EVS) was first fielded in 1981 in 10 Western European countries. The motivation for creating the EVS came from the sociology of religion, its funding from a private foundation. With basic moral and social values at its core, the EVS focuses on politics only to a limited extent, alongside topics like family, work, leisure time, and religion. The EVS is conducted every 9 years. The last 2008 study covered 47 countries and regions of Europe. The data are freely accessible via the GESIS data archive. While the EVS still goes on, it also branched out into the World Values Survey (WVS), a global investigation of change in social and political values (Esmer and Pettersson, 2007). Since its first wave of 1990–91, the WVS has become the most extensive program of academically driven international survey research. In its five waves, the WVS has covered 80 countries on all continents. What sets the WVS apart from all other academic international programs of comparative survey research is both the high number of participating countries and the fact that it consists of specially conducted surveys. Other programs aiming for worldwide coverage (CSES and International Social Survey Program (ISSP)) are attached to previously existing national programs of survey research. The WVS also seeks to study both democratic and authoritarian countries. Like the EVS, its substantive scope goes beyond political participation and citizen orientations. It also covers topics such as gender roles, work motivations, social capital, tolerance, and well-being. The WVS distributes the data itself. Assemblies of representatives of participating countries govern the EVS and the WVS.

The second strand of data collection programs relevant to the study of political behavior grew out of the American GSS, a study inspired by the social indicators movement of the 1960s and first fielded in 1972 (Smith et al., 2006). Created for the purpose of building an academic social science infrastructure covering a wide range of major research areas of sociology and political science, the GSS adopted a number of basic principles. They include a commitment to the highest methodological standards in every aspect of the survey process, and responsiveness to the data needs of the social science community as well as free, equal, and timely sharing of all data. Another crucial feature is a content philosophy of carefully balancing regularly repeated and innovative instruments. This is to allow for both a continuous monitoring of societal trends on the basis of identical questions and investigating new phenomena respectively new research questions. Great value is placed on detailed and extensive measurement of demographics. The GSS was run annually until 1994 and has been run biennially since then. As a replicative cross-sectional random sample face-to-face survey of the general population, the GSS samples a number of respondents large enough to allow for analyses of important subgroups of society. It is conducted by the University of Chicago's National Opinion Research Center. Like the ANES, it is funded by the NSF as a 'national scientific resource' and directed by Principal Investigators and a Board of Overseers. Similar to the ANES, the GSS quickly gained a reputation as the 'gold standard' in its field. In order to fulfill its promise to become a 'general' instrument, over the years, the GSS has covered numerous fields of interest to social science researchers, including political attitudes and participation, as well as many other topics.

The GSS also quickly became a model for similar programs in other countries. The biennial German ALLBUS was established in 1980 and the annual British Social Attitudes series was founded in 1983. Both studies follow the same principle of combining modules of repeated and new instruments. Similar studies were also created in Australia, Poland, Taiwan, Japan, Korea, and in 2003, even Mainland China. Not unlike the CSES in the field of election studies, networking between various GSS-type national survey programs eventually led to the creation of the ISSP. Since its inception in 1985, the number of member countries has grown from 6 to around 50. The ISSP fields a new survey every year, as a short add-on to a preexisting survey program. The annual modules usually focus on one topic, and most of them are rotated in cycles of around 10 years to allow for long-term comparison. While the national GSS-type studies are conducted via face-to-face interviews, the ISSP combines different survey modes. ISSP data are freely available via data archives like GESIS, both in combination with their national 'carrier' surveys, and as integrated multinational data sets (Haller et al., 2009). The ISSP has a Secretariat but is otherwise rather loosely structured as a network funded by member countries and directed by the assembly of all members. The utility of the ISSP for analyses of political attitudes and behavior depends on the specific research questions. Owing to the add-on principle, which is, of course, vital for its feasibility, its thematic scope is more limited than that of full general social surveys. Alongside themes like social inequality, religion, environment, family, gender roles, or health, past waves of the ISSP have repeatedly included modules on the 'role of government', as well as on national identity and citizenship.

The latest addition to the panoply of internationally comparative survey programs is the European Social Survey (ESS). In everything except coverage (which is not global but

mostly restricted to one continent), it is by far the most ambitious international survey project. In a nutshell, the ESS aims at running a fully fledged comparative survey in a large number of countries in Europe and beyond (Turkey and Israel) with all the substantive and methodological attributes established as hallmarks of the best existing national GSS-type studies (Jowell et al., 2007). In terms of rigor, effort, governance structures, and transparency, the ESS goes to great length to generate data without the substantive and methodological compromises that have to be faced by more modestly funded programs like the ISSP and even the EB. Since 2002, the ESS has completed six biennial rounds of data collection. Its content consists of fixed batteries of questions that are regularly repeated and two rotating modules per wave that are based on competitive proposals from the scientific community. In addition to cumulations of survey data, the ESS also provides users with several kinds of data for context analyses: regionally aggregated data from the survey itself, from various providers of official statistics, and from media-based data on situational circumstances.

While the respective national science foundations have awarded funding for the surveys, the ESS has also received substantial support for central functions of coordination and quality control by the European Science Foundation (ESF) and the European Union. Responsibility for directing the study rests with a Core Scientific Team coordinated by the Center for Comparative Social Surveys at City University London, which obtains advice from a specialized Methods Group and a multinational Scientific Advisory Board composed of representatives of participant countries, the European Commission, and the ESF. In 2005, the ESS received the prestigious Descartes Prize of the European Commission. In 2013, the ESS was officially granted the status of a European Research Infrastructure Consortium (ERIC), which implies its institutionalization as a survey program and will lead to changes in its funding and organizational structure.

Implications and Challenges

Over the last few decades, networks of entrepreneurs in the social sciences have accumulated a wealth of survey data on political behavior and citizens' orientations toward politics, mainly during elections, but also in nonelectoral contexts. To a large extent, this was, in effect, altruistic work, since foremost among its aims was the creation of data infrastructure for the scientific community. In several respects, comparative survey research on political behavior and other key areas of research in the social sciences has reached a new level with the creation of the ESS. This has established a standard against which other programs will be measured in the future but which is extremely difficult to meet because it presupposes enormous investments not only in terms of time and energy on the part of participating researchers but also above all on the part of funding agencies. If there is something like 'big science' in the social sciences, it consists of programs such as this one. Judged by what they achieved for the scientific community with very modest resources, studies such as ISSP and CSES are miracles of scientific and organizational ingenuity and efficiency. The dependency of ambitious national election studies or GSS-type surveys on very significant funds (at least by social science standards) makes them vulnerable to political and administrative interventions, as evidenced by the recent threats to the existence of the ANES. Although the proliferation of academically driven comparative surveys has significantly improved the conditions for research into comparative politics, it also poses many methodological challenges. Minimizing survey error is a daunting task even in quality-conscious single-nation studies, since social, technological, and legal changes constantly alter the conditions under which surveys are conducted. Cross-national research multiplies these difficulties and adds new ones, in particular, the many precautions required to establish cross-national equivalence between surveys with regard to all aspects of their production process. Several comparative survey programs have openly addressed this challenge and contributed significantly not only to substantive but also to methodological research (Harkness et al., 2003, 2010). At least in advanced industrial democracies, it seems, in principle, feasible to aim for fulfilling the strict requirements of the 'best practices' identified by this research field, as the example of the ESS demonstrates. However, it appears doubtful whether these benchmarks are feasible for less developed countries, which are high on the agenda of programs like the WVS. Another foreseeable challenge to both national and international replicative survey programs concerns their relationships to one another. As the number of infrastructure programs increases, calls will emerge demanding more coordination between them. Sooner or later, some of them may even find themselves in competition with one another for scarce funds. Since questionnaire space is limited, finding the right balance between continuity and change in instrumentation has always been a standard problem for replicative surveys of any kind. However, against the background of on-going social differentiation and individualization, a situation may be envisaged where even extensive surveys may no longer be able to carry all instruments needed for adequately measuring social and political phenomena in all their growing complexity. It may become necessary to supplement them with new data collection instruments and to develop new techniques for fusing independently collected data.

Abstract

This article describes the historical background of developments in political science, which have paved the way for longitudinal comparative surveys and the concept of databases and data archives from the 1950s on.

The initial situation of survey data scarcity in the social sciences has been replaced by a situation of data richness accessible through data archives and other data holding organizations. The article specifically looks at core contemporary projects providing survey data for longitudinal and comparative research with increasing options for micro–macro multilevel analysis as an important element of innovation in empirical political science research.

Data generally give information about units of analyses and/or observations, and are at the center of empirical political science analysis. Data can either come from administrative processes like censuses, or are created by scholars through systematic obtrusive or unobtrusive techniques. Databases are generalized or focused collections of datasets, as held, for example, by data archives. The systematic production of political science data has been stimulated especially through the study of political elections. Based on new survey methodologies, such studies originated in the United States after the Second World War and later spread to Europe and to other parts of the world. International cooperation between leading social scientists improved and facilitated data analysis due to the increasing number of data archives, which permitted free access to datasets. Free access to datasets also encouraged secondary data analysis since existing data could be examined from different aspects and perspectives. At the turn of the twentieth century, the initial scarcity of data was replaced by data abundance not the least through international data archive cooperation which also permitted analyses across time and nations. Thus, empirical political science has been gaining a strong historical dimension. This development is supported by data collections such as the General Social Surveys (GSS) and National Elections Studies nationally, and the International Social Survey Programme (ISSP), the various international Barometer studies and the World Values Surveys (WVS) internationally.

Data and Databases

Data are information on units of analysis or observation. These units can be individuals (micro), organizations like businesses or political parties (meso), or nations (macro). Data can be divided into geographical units like cities, counties, or states, or they can even describe relations like elite networks. Often, units of analysis and units of observation are the same. However, sometimes units of observation, like all family members in a household, can be aggregated if the household is the unit of analysis.

In political science, data are collected through a variety of means. They can be process produced in administrative environments, such as macro or microcensuses for the purposes of societal self-observation and informed policy formation, or they can be created according to (more or less) methodologically sophisticated approaches by scientists, for example, through questioning individuals or other social units, so-called obtrusive techniques. Data can also be derived from unobtrusive techniques like content analyses of printed or video material as well as group observations.

Information on a particular collection of units of observation or analysis placed in a specific time frame and space is called a dataset. Correspondingly, databases are general or focused collections of datasets, as held, for example, by data archives.

The Beginnings

Developments during and after the Second World War

In his account of the history of political science, Almond (1996) pointed out that in the context of the professionalization of the field in the twentieth century, the empirical study of political phenomena blossomed already in the first decades, most noteworthy in the Chicago School, which is associated with such eminent scholars like Charles E. Merriam, Harold Gosnell, and Harold D. Lasswell. He emphasizes, though, that a major breakthrough in the theory, methodology, and practice of empirical political science research was accomplished after the end of the Second World War. During the war, many of the later leading figures in the social sciences were employed in a variety of US government or related public and private organizations with the task to find answers to questions of critical military and civilian importance in the war context. One case in point is the series of four seminal studies of *The American Soldier* directed by Samuel A. Stouffer who surveyed during World War II more than a half million American soldiers to find out about their emotional life, their behavior in combat, and the way they saw their role and position in society.

The Institute for Social Research

The above research was a part of the context, which in the long haul also helped the foundation of the Institute for Social Research (ISR) at the University of Michigan in Ann Arbor by scholars like Angus Campbell, George Katona, Rensis Likert, and Robert Kahn. In 1952, Campbell and Kahn published

 http://dx.doi.org/10.1016/B978-0-08-097086-8.41019-6

a small book on the US presidential election of 1948, which is noteworthy because this first election study by the Michigan Survey Research Center (SRC) was one of the very few, if not the only one which correctly accumulated and analyzed data that proved Truman's win over Dewey. Furthermore, it was innovative in that it was national in scope, used a fairly sophisticated method for selecting respondents, applied a pre–post panel design and operated with a majority of standardized, but also some open-ended questions.

This study is singled out not only because it very well reflects the beginning theoretical and methodological innovations in research on political behavior, but also because it paved the way for one of the most demanding ventures in database construction: the American National Election Studies (ANES).

The American National Election Studies

ANES is a collaborative project producing data on voting and political participation in the United States. Warren E. Miller (1994: pp. 249–250) points out in his recapitulation of the history of ANES that the outcome of the 1948 presidential election resulted in "a public embarrassment to the national community of public opinion pollsters" (because of their falsely picking Dewey as the winner). The successful Michigan study correctly predicting the outcome of that election gained remarkable public and scholarly visibility, resulting in a grant to the Social Science Research Council (SSRC) which in turn commissioned the SRC to also conduct a study of the 1952 presidential election. With the intellectual success of this study (Campbell et al., 1954), the ground was prepared for a continuous series of Michigan-based election studies which finally were transferred into the format of the national political science research resource of the ANES (Miller, 1994: pp. 260–262) funded by the National Science Foundation since 1977.

Influence on European Social Science

The intellectual pull of the Michigan school of electoral research was felt not the least by European political scientists who especially in the 1950s and 1960s came to Ann Arbor to learn about the study of elections and about advanced methods in social research. It is because of this connection that in a fair number of European countries national election studies became institutionalized from the 1970s onward (for an account of this see Thomassen, 1994). What made this development so pertinent is that the Michigan–European interaction helped to prepare the ground for the most important development in creating political science databases: the emergence of academic data archives.

Data Archives – A Core Infrastructure for Political Science

The Necessity of Data Archives

The emergence of academic social science data archives reflects very much the state of empirical political science in the 1950s and 1960s. First, the methodology of social research and particularly survey research had been advanced to a point where it was regarded as a reliable, fruitful way of collecting information on a broad variety of social and political topics found interesting by the research community, but also by social and political elites as well as by the mass media (e.g., see Lazarsfeld and Rosenberg, 1955; Hyman, 1955). However, the time period for which survey studies were then available was still quite short. Therefore, one-shot studies, usually of a cross-sectional nature, meaning the analysis or observation of a unit at a specific point in time, and not of a longitudinal nature, meaning repeated observations over longer periods of time, dominated the field. In addition, high-quality surveys were expensive, funding opportunities were limited, and therefore access of the academic community to such information was difficult. The resulting scarcity of data plus the growing insight that primary investigators were not capable of completely exhausting the analytical potential of a given dataset, paved the road for considerations to make data which were often paid for by public money and therefore in principle a collective property available also to other than the primary investigators after those had their first good shot at data analysis and publication. A further point is also relevant. Often, data collected by primary researchers under a specific conceptual scheme can be reanalyzed under a vastly different scheme and may lead to new insights. Thus, the logic of secondary analysis (Hyman, 1972) of existing data was an important addition to the arsenal of empirical political and social research and triggered an increasing demand for such data. Thus, data archives were the answer to many concerns resulting from the data needs of empirical political science. It is little wonder then that already in 1966, Ralph L. Bisco (1966: p. 93) could speak "of a growing movement within the social sciences: the creation of repositories of social science data."

The Inter-University Consortium for Political and Social Research

There is an agreement in the literature that the oldest general-purpose survey data archive in the world is the Roper Center for Public Opinion Research (Bisco, 1966: pp. 96–97). It was founded in 1947 at Williams College and is now located at the University of Connecticut in Storrs holding data going back to the 1930s. While in many ways it has served as an example for other data archives founded later, the impact of the Inter-University Consortium for Political and Social Research (ICPSR; initially ICPR) at the ISR on the development of data archives in Europe has been more pronounced because it could build on an identity of substantive research interests between American and European scholars.

In his recollection of the foundation of the ICPR, Miller (1989: pp. 152–153) mentions the intersection of two important strands of thought regarding the improvement of the political research infrastructure. The first was the positive impact on the development of at least parts of political science in the United States from the Michigan election studies and, more concretely, from two summer seminars held at the SRC in 1954 and 1958 which were sponsored by the SSRC Political Behavior Committee.

"The attraction of the courses was the ability to analyze the Survey Research Center election surveys with state-of-the-art counter-sorters which were not available at most other campuses" (Weisberg, 1987: p. 282).

Second, in the interaction between the SRC and Stein Rokkan, one of the great European social scientists and comparativists, the SRC took up ideas from a Rokkan report to the Ford Foundation in 1957, proposing the establishment of survey data archives particularly to stimulate comparative research (Rokkan, 1964: pp. 49–62, 1966).

Zentralarchiv für Empirische Sozialforschung

The foundation of the Zentralarchiv für Empirische Sozialforschung (ZA) at the University of Cologne, Germany, preceded the 1962 establishment of the ICPR in time. The ZA was established in 1960 by Guenther Schmoelders, a professor of public finance with many links to the United States and especially George Katona and was later directed by Erwin K. Scheuch, a major figure in international cooperation in the social sciences and in comparative research. Both ICPR and ZA were pioneers in academic data archiving and cooperated closely from their early days on. This innovation owed a lot also to the network of the Committee on Political Sociology of the International Political Science Association and of the International Sociological Association, which brought together scholars like Campbell, Philip E. Converse, Juan Linz, Seymour Martin Lipset, Richard L. Merritt, and Miller from the American and Hans Daalder, Mattei Dogan, S.N. Eisenstadt, Arend Lijphart, Giovanni Sartori, Scheuch, Otto Stammer, and Jerzy J. Wiatr from the European side.

Other European Data Archives

In Europe, other archives followed the Cologne ZA in due time, among them in 1967 the UK Data Archive at the University of Essex in Colchester and in 1971, very much by Stein Rokkans doing, the Norwegian Social Science Data Services (NSD) at the University of Bergen. The latter deserves special mention because its founding was embedded in the establishment of the European Consortium of Political Research in 1970, and was entrusted with the difficult task of stimulating social science data archiving in Europe (Newton and Boncourt, 2010: p. 11). This effort bore fruit when in 1976 the Council of European Social Science Data Archives (CESSDA) was founded (Mochmann, 2009: pp. 491–493; http://www.cessda.org). This organization now (fall 2012) embraces 21 national data archives in Europe and presently is in the difficult process of being transformed into a European Research Infrastructure Consortium (ERIC). This transformation is so important because it promises to put the funding of the national archives on a safe European footing.

It should be added that there is also a worldwide association of social science data organizations (IFDO – International Federation of Data Organizations for Social Science – http://www.ifdo.org). It has more than 30 members with a substantial overlap with CESSDA, but embraces seven members from the United States.

The Historiographic Dimension of Longitudinal Data

In one of his many insightful contributions to the social sciences, Paul F. Lazarsfeld (1972 (1964)) put himself into the role of a 1984 historian and asked about the obligations a 1950 pollster has vis-à-vis this historian. One can carry this torch much farther now in observing that especially data from survey research have opened up a new dimension in historic analysis along the lines of social history. With the advent of representative sample surveys of national population or special subgroups in society, the potential for the *ex post* understanding of microphenomena of an attitudinal as well as of a behavioral nature has been vastly enhanced, and examples of excellent historical analysis based on findings from longitudinal sample surveys are increasing in number (see for instance the analysis by Schildt (1995) on the modernization process in postwar West Germany).

But there is much more to be gained analytically from data, which reach back into the past, and this is even truer when the researcher's interest is in more than one country. In the late 1980s, after heated controversies especially in Europe about the future of democratic government, a stocktaking of public attitudes toward European governments took place between 1989 and 1994 through the Beliefs in Government project directed by Max Kaase and Kenneth Newton (Kaase and Newton, 1995; Abramson and Inglehart, 1998) and solely based on secondary survey data. Obviously, this project would not have been possible without systematic recourse to existing databases held in European data archives. Still, at the same time a number of shortcomings and weaknesses in the availability, equivalence (van Deth, 1998), and quality of the data showed when becoming longitudinal and at the same time comparative in perspective.

Since the 1990s the survey data situation for longitudinal and comparative research has improved to an extent not deemed possible before (Heath et al., 2005; Kittilson, 2007; Norris, 2009). Not all of the data, which are now collected at regular intervals, are directly tuned to political science interests. But all of the collections, which will be addressed later hold information which can be used also for political science topics.

Most of those studies pertain to the individual as unit of analysis, and most of them are done as independent cross sections of the population that is targeted. One important exception is the household surveys conducted in the United States and in some European countries since the 1970s where the unit of analysis is the household and where all members of a given household from a certain age on are included in the study design (Schupp and Frick, 2010). What makes these surveys so complex and expensive, though, is that the studies are conducted as panels where the goal is to interview the same persons across time and thereby measure individual change across time.

Cost is one of the reasons why social researchers are turning away from personal interviews to telephone interviews once the telephone coverage in a given country or population has reached a point where representative sample surveys can be affected. The same situation pertains to Internet surveys, which become increasingly popular. However, whether and when they will become a cost-effective, methodologically satisfactory and probably an altogether superior mode of data collection is an open question (Smyth and Pearson, 2011); to apply them in comparative survey research certainly is a long distance away. And this is even more true for Internet panels capable of assessing individual change across the time dimension. Still,

the Longitudinal Internet Studies for the Social sciences panel in the Netherlands, which started in October 2007, is a project which shows that a representative panel study can be successfully conducted when the necessary resources are invested.

Core Databases in Social Sciences

Reasons for the Abundance of Databases

It was mentioned in the beginning that by the turn of the twentieth century, the initial data scarcity in the social sciences has been replaced by a situation of data richness. There are many reasons for this. With economic growth especially in the Organisation for Economic Co-operation and Development countries since the end of the Second World War, the number and/or size of educational institutions has risen dramatically with larger student populations (measured by shares in birth cohorts), and with this also the number of researchers both within and outside of institutions of higher learning. This development has, of course, embraced the social sciences too, and with more research money around the number of academically driven data gathering research projects has increased substantially. Also, a large number of empirical social science studies is regularly conducted on behalf of and paid for by government agencies, the media, and for private business, often with advice from the academic community. Therefore, quite a few of these data also find their way into academia, and this means mostly through data archives. A specification of which core databases in political science presently exist has to be taken according to explicit criteria. For the purposes of this article, the main selected criteria are political science content, emphasis on microdata stemming from representative sample surveys, longitudinality, international scope, and free data availability through academic data archives. In the following, only the most important such databases will be addressed.

For completeness sake it should be added that there are also macro and aggregate political science databases like the one produced by the Comparative Party Manifestoes Project (Budge et al., 1987; Klingemann et al., 1994). Very pertinent are the databases related to the study of democracies and a more recent emphasis on the quality of democracy (most of these databases are covered in an article by Coppedge et al., 2011). One more recent effort not included in the above discussion is the democracy barometer developed by a group of scholars from the University of Zuerich and the Berlin Social Science Center (Buehlmann et al., 2011).

International Comparisons of National Election Studies

For political scientists the most pertinent data come from the various national election studies, in particular from the ANES. They aim at the heart of the democratic political process – elections – and are longitudinal in nature. The opportunity to look at the electoral process comparatively is provided by these data to the extent that there are enough at least functionally equivalent questions asked across nations and different institutional and political settings to make an international comparison meaningful at all. These claims have been optimally realized by the project Comparative Study of Electoral Systems (CSES; http://www.cses.org). This is a project conceptualized by the International Committee for Research into Elections and Representative Democracy aiming at covering free elections in all parts of the world. This is done since 1996 by attaching a special questionnaire to the post-election studies conducted in the participating countries. Three modules have been fielded in 1996–2001, 2002–06, and 2006–11 emphasizing three different topics. These data covering more than 50 countries are not easy to use because of the widely differing institutional setup of the participating countries, differences in their number and the logical time lags between countries and elections. One big asset is the availability of macro data permitting multilevel analyses (Heath et al., 2005: p. 301; Norris, 2009: pp. 529–530; Klingemann, 2009).

GSS and the ISSP

In 1972, the first GSS was started at the National Opinion Research Center at the University of Chicago. This program was extended through collaboration between research groups from Germany, the United Kingdom, and Australia. Most important, however, was the effort by scholars from these four countries to develop a program of systematic international cooperation, the ISSP (http://www.issp.org). This is a program of comparative survey research, which is defined by drafting groups, which are responsible for the selection of topics to be attached as modules to annual national surveys of the GSS kind and to be repeated for longitudinal analysis in regular intervals (for instance, the module 'role of government' has been run in 1985, 1990, 1996, and 2006). ISSP started with six countries and in 2013 embraced 48 countries from different parts of the world.

Barometer Series of Data Collections

The series began with the Eurobarometers (http://europe.eu.int/comm./public_opinion/index_en.htm). Eurobarometers measure public opinion of certain topics and issues related to the European Union. These are representative sample surveys with usually about 1000 respondents conducted twice a year since 1974 in all countries of the European Union. As the number of EU member countries has grown over the years, so has the number of nations covered by the Eurobarometer. While many of the questions are concerned with special information needs of the European Commission, the data contain enough continuous information on politics to make them very attractive for political scientists (e.g., see Kaase and Newton, 1995). Also, since the demise of communism, comparable surveys have been regularly conducted in Central and Eastern Europe (Eurobarometer East). Furthermore, the Eurobarometer has served as an example for similar surveys around the globe. In the following, the presently (2012) existing barometer data collections are just listed with their web addresses (for details see Heath et al., 2005: pp. 302–314; Kittilson, 2007: pp. 881–887; Norris, 2009: pp. 531–532):

- Afrobarometer (http://www.afrobarometer.org/)
- Arab Barometer (http://www.arabbarometer.org)

- Asia Barometer (http://www.asiabarometer.org/)
- Asian Barometer (http://www.asianbarometer.org/)
- Latinobarometro (http://latinobarometro.org)
- New Baltic Barometer (http://balticvoices.org)
- New Europe Barometer (formerly New Democracies Barometer) (http://www.abdn.ac.uk/cspp/).

Four of the regional barometers (Africa, Asia, Latin America, and the Arabic region) have joined forces to collaborate on substantive and methodological research concerns (http://www.globalbarometers.org).

The European/World Values Surveys

In 1981, the European Values Study Group was founded at the University of Tilburg, the Netherlands. Aim of the study was to examine human values, opinions, and attitudes of European citizens. The group started with surveys in 10 West European societies. The findings of this study were regarded as so interesting that a decision was taken to replicate the study in 1990, but at the same time to enlarge its geographical scope thus becoming the WVS. The second wave of surveys was coordinated by Ronald Inglehart between 1989 and 1993 and already covered 41 nations in all parts of the world. A third wave of surveys was carried out between 1995 and 1998 in 55 countries, the fourth wave of surveys was conducted between 1999 and 2001 in 59 countries, to be followed by a fifth wave between 2005 and 2007 in 87 countries. The sixth wave of surveys conducted between 2010 and 2014 will cover at least 50 countries.

While in total almost 100 countries have participated at least in one survey, the logic of the flexible WVS organization results in a variable geometry regarding country continuity. Details can be found in looking at the project's website also regarding how to access the WVS data (http://www.worldvaluessurvey.org/). There is no question that the WVS is the most encompassing longitudinal and comparative study of values and beliefs worldwide resulting in a plethora of publications. Given the range of countries with very different politicoinstitutional arrangements and value systems, one great asset of the WVS will be its potential for micro–macro multilevel analyses.

The European Social Survey (http://www.europeansocialsurvey.org/)

The Beliefs in Government project (BiG – Kaase and Newton, 1995) mentioned before was the first study, which aimed at analyzing sociopolitical change in postwar democratic Europe and was based exclusively on secondary survey data. The project's vision was to fill a three-dimensional matrix of country, topic, and time, but it soon found out that the available secondary data were not sufficient to reach this goal. This experience was the basis to establish, in the context of the European Science Foundation, a plan to establish a high quality comparative longitudinal survey in Europe (Jowell et al., 2007). Since 2002, the survey is conducted every second year in about 25 European countries, Turkey, and Israel, and applies rigorous methodological standards (Norris, 2009: p. 532). As of now, six rounds of surveys have been conducted (2002, 2004, 2006, 2008, 2010, and 2012). The European Social Survey (ESS) is a combination of a set of core questions to be repeated in every round, and two rotating modules on a variety of different topics (although some rotating modules have already been replicated) which are awarded to European social scientists in Europe at no cost based on a Europe-wide competition. The ESS in all its facets is documented at the highest possible level by the NSD; all data can be directly downloaded from the ESS website at no cost as soon as the surveys are available. The ESS has also from the beginning aimed at opening the road for multilevel analyses, an option which is eased by the availability of contextual data also stored at the NSD. The complex organizational structure of the ESS is, under the auspices of the European Commission, in the process of being transformed into an ERIC which should stabilize its existence.

Perspectives

The abundance of survey data for comparative longitudinal research does not automatically imply that the quality and documentation of the studies is beyond any doubt (Heath et al., 2005: pp. 314–330; Norris, 2009: pp. 535–538). Thus, using such data will require a very considerate approach in conducting analyses, not to speak of new data sources emerging, for example, from facebook which, if becoming available for social science analysis, will require completely new approaches to data analysis. But even more so, the social sciences in general will be experiencing major challenges in many areas, be they conceptual, legal, substantive, methodological, or technological in nature (German Data Forum (RatSWD), 2010).

Summary

Empirical political science over the last 70 years has traveled a long distance from its modest beginnings when ideas of secondary data analysis and for organizations holding, documenting, and making accessible at no or little cost datasets of general interest to researchers began to thrive. Initial situations of data scarcity particularly in survey research have now been replaced by data wealth, creating new and interesting challenges for researchers basing their scholarly work on empirical data from these of sources. In this article, not only has the situation leading to such abundance been sketched out, but also information on the major databases presently in use by the political science research community has been summarized.

Since this information is now not only exploited in research, but also in teaching and policy making, it is now just a question of time to see whether there will be a measurable impact on the better understanding of the dynamics of the social, cultural, and political process in democratic as well as nondemocratic polities, with the concept of nation states still in their center. It will remain to be seen whether the achievements described in this article will keep and enhance their impact on political studies and will remain indispensable instruments of social science analysis or whether they will become standard folklore and lead the way to new frontiers in political science research.

Data Bases and Statistical Systems: Security and Conflict

Thomas Wencker, Christoph Trinn, and Aurel Croissant, University of Heidelberg, Heidelberg, Germany

Abstract

'Conflict and security statistics' refers to empirical data collected and processed for the quantitative and qualitative analysis of the causes, dynamics, and consequences of international and intranational conflicts and for policy making with regard to early warning, risk assessment, as well as conflict and postconflict management. Security in a broader sense refers to the safety from chronic threats to individual integrity and vital freedoms in physical, socioeconomic, and cultural dimensions. Concepts guiding quantitative approaches to conflict and security encompass armed or political conflict, dispute, war, terrorism, human rights violation, genocide, and coup d'état. Research has recently advanced with regard to its empirical scope and data disaggregation. However, challenges related to further disaggregation, the linking of datasets, and the availability and reliability of data remain.

Introduction

'Conflict and security statistics' refer to empirical data collected and processed for the quantitative and qualitative analysis of the causes, dynamics, and consequences of international and intranational conflicts and for policy making with regard to early warning, risk assessment, as well as conflict and post-conflict management. In empirical conflict and security studies, however, the focus is often narrowed to protection from organized violent threats to individuals. Political conflict is the incompatibility between social systems with regard to the security of a population, the integrity of a territory, or the maintenance of a political, socioeconomic or cultural, and national or international order. The concept of political conflict therefore does not include phenomena such as domestic violence or homicide. Conflict and security statistics generally focus on the international and national political systems (systemic levels), and on conflicts either between nonstate and governmental actors, resulting in intranational or transnational conflicts, or among nonstate actors, known as subnational conflicts (configurational levels).

The History of Conflict and Security Statistics

The Origins of Modern Conflict and Security Statistics

The origins of modern conflict and security statistics can be traced back to compilations like P. Quincy Wright's 'A Study of War' (1942) and Richardson's 'Statistics of Deadly Quarrels' (1960). In 1963, the first professional association in the field of statistical analyses of conflicts and security was founded in Malmö, Sweden. Renamed the Peace Science Society (International) in 1973, it is now based at the Pennsylvania State University. Also in 1963, J. David Singer founded the Correlates of War Project (COW) at the University of Michigan (now hosted by Pennsylvania State University). COW was among the first to apply quantitative criteria in defining conflicts, introducing a threshold of war of at least 1000 battle-related fatalities of troops in combat.

In the 1980s, prominent European conflict research institutes were founded. The first one was the Uppsala Conflict Data Program (UCDP), which stands in the tradition of COW's quantitative definition of war. Since 2004, UCDP has closely collaborated in the development of, and data collection for, the 'Armed Conflict Dataset' (ACD) with the Peace Research Institute Oslo (PRIO, founded in 1959). In addition, both PRIO and UCDP have started georeferential conflict data coding: PRIO with its 'Armed Conflict Location and Event Dataset' (ACLED) and UCDP with its 'Georeferenced Event Dataset' (GED). In the early 2000s, new hubs of conflict and security statistics emerged at the ETH Zürich (Lars-Erik Cederman) and the University of Essex (Kristian Skrede Gleditsch).

In contrast to the Scandinavian tradition, two German research institutes have turned away from COW's quantitative approach. Instead, the Arbeitsgemeinschaft Kriegsursachenforschung (AKUF) at the University of Hamburg, established in 1986, and the Heidelberg Institute of International Conflict Research (HIIK), founded in 1991, focus on the quality of conflict processes and structures, broadening the conceptualization and measurement of conflict. Until 1998, the HIIK maintained the Konflikt-Simulations-Modell (KOSIMO) dataset, a spin-off of which is the Conflict Information and Analysis System (CONIAS) at the University of Heidelberg, in existence since 2005. Since 2011, CONIAS and HIIK have moved toward spatial and temporal disaggregation of their conflict data.

Initiated by Ted R. Gurr, in 1994 the State Failure Task Force was established. Renamed Political Instability Task Force (PITF), it is a research panel funded by the US Central Intelligence Agency and concerned with state failure events manifested in revolutionary wars, ethnic wars, contested regime changes, and genocides. It is closely related to the Major Episodes of Political Violence (MEPV) dataset by the Center of Systemic Peace (CSP), an institution founded in 1997 and especially known for the Polity regime datasets.

Among several other datasets on conflict and security are, in particular, the civil war compilation by James D. Fearon and David D. Laitin (2003), the Armed Conflict Database by the International Institute for Strategic Studies in London (since 1958), as well as the International Crisis Behavior Project dataset by the Center for International Development and Conflict Management (CIDCM) at the University of Maryland.

 http://dx.doi.org/10.1016/B978-0-08-097086-8.41076-7

CIDCM is also home of the Minorities at Risk (MAR) Project, established in 1986 by Ted R. Gurr, on politically relevant ethnic groups and organizations and ethnopolitical conflicts.

Extensions toward Other Forms of Political Violence

In addition, more specific forms of political violence such as terrorism, human rights violations, genocide, and coups d'état have also become subject of conflict and security statistics in recent years. With regard to terrorism these include

- the Global Terrorism Database (GTD) by the National Consortium for the Study of Terrorism and Responses to Terrorism (START), founded in 2005 by the US Department of Homeland Security;
- the GTDs I and II as provided by the National Archive of Criminal Justice Data (NACJD);
- the Terrorism and Preparedness Survey Archive, jointly managed by START and NACJD and funded by the US Departments of Justice and Homeland Security;
- the High Casualty Terrorist Bombing Events (HCTB) dataset by CSP;
- the International Terrorism: Attributes of Terrorist Events (ITERATE) database;
- the RAND Database of Worldwide Terrorism Incidents (RDWTI).

Furthermore, the Cingranelli-Richards (CIRI) Human Rights Dataset and the Political Terror Scale (PTS) contain information on government respect for internationally recognized human rights, political violence, and terror. With regard to genocides and other instances of mass killings of civilians, Barbara Harff and Gurr in 1988 developed a comprehensive data collection of genocides and politicides since the Second World War. Benjamin Valentino compiled a list of mass killings of civilians in the twentieth century in 2000. Since 1994, the State Failure Task Force's State Failure Problem Set also includes data on genocides and politicides. Based on these data, Harff published a risk assessment model in 2003, which is regularly updated. Apart from these efforts with a global scope, the Yale University-based Genocide Studies Program (GSP, founded in 1998) hosts case-oriented databases on the genocides in Cambodia, Rwanda, East Timor, Guatemala, and the Former Yugoslavia.

Finally, since the 1960s, data on coups d'état were compiled for the purposes of specific analyses and presented in the appendices of articles or books investigating their causes, types, and consequences. In 2007, Monty Marshall and Donna Marshall of CSP developed a comprehensive coups dataset that is regularly updated. In 2011, Jonathan M. Powell and Clayton L. Thyne compared and merged 14 existing datasets on coups into a single dataset. Their work is also considered in the recent update of the CSP coup d'état events dataset.

Concepts and Measurement

Definitions of Political Conflict

Researchers employ different terms to label the empirical phenomena under investigation. The choice of a specific term is important as it influences academic and public debates that may arise around conflict and security statistics. On the most fundamental level, these terms encompass 'war,' 'armed conflict,' 'political conflict,' 'militarized interstate dispute (MID),' 'major episode of political violence,' or 'ethnopolitical conflict.' Pertaining to similar phenomena, the terms are situated on different levels of abstraction and emphasize specific characteristics of political conflicts. The level of abstraction and the number of defining attributes shape the extension of the concept, i.e., its empirical scope. Some institutions use specific terms such as 'war' or 'crisis,' whereas others employ wider definitions of political conflict and build subtypes. Widespread, although not ubiquitous, is the reference to three dimensions of conflicts: conflict actors, conflict items, and conflict measures. A possible fourth dimension, the intensity of conflicts, is a property derived from the (inter)actions of the conflict parties and can be subsumed under conflict measures.

The COW project's definition of 'war' presupposes three necessary attributes: sustained combat, the involvement of organized armed forces, and a death toll of at least 1000 battle-related fatalities within a 12-month period. The implementation of a threshold of fatalities has deeply influenced subsequent research. It is the single most influential attribute and indicator to identify and differentiate types of violent political conflict.

Similar to COW's definition of 'war,' CSP defines 'MEPV' as periods in which organized groups engage in systematic and sustained use of lethal violence resulting in at least 500 directly related deaths over the course of the period. UCDP employs an even lower threshold in their definition of 'armed conflicts' (synonymously 'state-based conflicts'). 'Armed conflicts' require the occurrence of at least 25 battle-related deaths in a calendar year. In addition, the definition rests on three necessary attributes: (1) the existence of an incompatibility over government or territory, (2) the use of armed force, (3) the involvement of at least one national government. What makes UCDP's definition distinct from other concepts is the inclusion of a specific conflict item as the object of incompatibility; 'armed conflicts' are either about the type of political system or the replacement or change of composition of the central government, or about the status of a territory. In its definition of 'nonstate conflicts,' UCDP drops the attribute of a specific type of incompatibility, but requires both sides of the conflict to be nongovernmental.

Concerning conflict measures, COW's 'war' definition is the most restrictive one as it employs the highest threshold of battle-related fatalities of the aforementioned concepts. The COW project, however, also includes conflicts below this threshold, labeled 'MIDs.' 'Militarized' refers to the threat, display, or use of military force short of war; 'interstate' excludes all those militarized disputes where at least one side is not a state; and 'dispute' refers to the contestation over unresolved issues. An 'MID' is instantiated by at least one 'militarized incident.'

MAR's founder Ted Gurr (1980) defines conflict as "the overt, coercive interactions of contending collectivities," i.e., the observable use of force between state or nonstate groups. CONIAS defines 'political conflict' as a positional difference with three attributes: (1) the difference exists among at least two decisive and directly involved actors; (2) their actions and communications lie outside established regulatory procedures

and threaten core state functions; and (3) the positional difference regards values relevant to a society.

Concepts of Specific Forms of Political Violence

Among the concepts covering threats of physical integrity and security are 'terrorism,' 'human rights violation,' 'genocide,' and 'coup d'état.' 'Terrorism' is a highly contested concept. CSP's HCTB dataset employs three attributes to define a terrorist event: (1) bomb attacks resulting in at least 15 fatalities, (2) civilian and political noncombatant targets, and (3) nonstate actors as perpetuators. START's GTD definition of terrorism rests on three necessary conditions: (1) perpetrators are nonstate actors who (2) use or threaten to use illegal force and violence to create coercion or intimidation in order to (3) attain a political, economic, religious, or social goal. The older GTD II, on which START's GTD is based, used a more elaborate definition. In particular, it stressed the communicative character of terrorist acts and defined illegal force as being outside the parameters of international humanitarian law. Employing four criteria, RDWTI defines terrorism as the use or threat of violence directed against civilian targets by a group or individual who aims at attaining a political goal by inducing fear.

CIRI defines violations of human rights as government disrespect for the physical integrity of individuals, for civil liberties, workers' rights, and gender equality. PTS measures state-sanctioned killings, torture, disappearances, and political imprisonment on a five-level pervasion scale. While both are similar regarding actors, PTS directly refers to the level of indicators.

CSP's compilation of genocides and politicides in the State Failure Problem List rests on the definition of Harff and Gurr, who use three attributes to define the two concepts: (1) the promotion, execution, and/or implied consent of sustained policies by (2) governing elites, their agents, or contending authorities in a civil war that are (3) intended to destroy, in whole or part, a communal, political, or politicized ethnic group. The criterion of defining the victimized group can be based on either communal characteristics (genocide) or as political opposition (politicides). The related phenomenon of mass killings is, according to Benjamin Valentino, defined by (1) a massive number of noncombatants killed, operationalized as 50 000 fatalities in a 5-year period, with (2) casualties caused intentionally and not considered as 'collateral deaths.' This includes the fatal consequences of direct or indirect use of violence, e.g., by creating conditions that cause fatalities.

Wider concepts of political conflict regard coups d'état as a subtype of intrastate political conflict. Accordingly, the concept of coup can be understood as a specification of the three defining attributes of political conflict. While the formulations and specifications vary, coups are usually defined as the use or threat of force by state elites aiming at overthrowing the government. Concerning the item, a coup d'état can be regarded as a conflictive form of regime or government change. Regarding measures, and contrary to more narrow concepts of violent political conflict, the actual use of violence is generally not regarded a necessary attribute of a coup d'état. However, definitions usually refer to the extralegality or the threat of force. Concerning actors, coups are defined as primarily originating from a country's elite, demarcating them from regime changes due to popular uprisings or external intervention. The definition of coup d'états by Marshall and Marshall draws on four attributes: (1) the use of force by (2) an oppositional faction within the country's ruling or political elites that leads to (3) the capture of executive authority and office, and (4) a substantial change in the leadership of the government and its policies. If the new government holds power for at least 1 month, a coup is categorized as successful. Powell and Thyne's new dataset focuses on coup attempts, i.e., (1) the activity is illegal, (2) it is undertaken by any elite, which is part of the state apparatus, and (3) it aims at replacing an incumbent government.

Empirical Scope

Most relevant for conflict and security statistics is the extension of the basic concepts, which derives from the extension of the individual attributes (conflict actors, items, and measures). Concerning conflict actors, 'war' (COW), 'MEPV' (CSP), and 'political conflict' (CONIAS) are the most extensive concepts. They subsume all possible constellations between state and nonstate actors within one term. UCDP differentiates two terms to refer to conflicts with or without state participation, whereas COW's MIDs only comprise disputes between states. MAR covers only conflicts involving ethnopolitical groups, i.e., ethnic identity groups that constitute the focal point of grievances and political action.

UCDP's definition of 'armed conflict' is restricted by two concrete conflict items (government and territory). MAR subsumes under the term 'ethnopolitical conflict' either inter- or intracommunal conflict, protest, rebellion, or government repression. The concepts of 'political conflict' (CONIAS) and 'MID' (COW) are more extensive, as they refer to items in a much more abstract sense, whereas 'war' (COW), 'MEPV' (CSP), and 'nonstate conflict' (UCDP) do not mention conflict items at all. Concerning conflict measures and their consequences, COW's 'war' definition is most restrictive with a necessary 1000 battle-related deaths in a 12-month period, followed by CSP's 'MEPV,' where the number of casualties is not linked to a specific time frame. COW's 'MID' include interstate disputes below the threshold of 1000 deaths. 'Political conflicts' in CONIAS include violent as well as nonviolent forms of conflicts. While MAR's definitions of inter- and intracommunal conflict and rebellion require the presence of (not necessarily fatal) violence, the categories of protest and repression include nonviolent actions, as well.

Whether to employ a broader or narrower definition of political conflict depends primarily on the research interest. While concepts with a larger empirical scope allow subsuming different forms of conflict under a single term, the entity under investigation may become less specific. A narrow definition, on the other hand, allows for more precise and extensive research with a smaller number of cases. Furthermore, concepts and corresponding datasets with identical institutional origin, such as COW's 'war' and 'MID' or UCDP's 'armed conflict' and 'nonstate conflict,' can easily be merged to form wider concepts. Wider conceptual approaches, in contrast, may increase specification by building subtypes through a within-differentiation of the attributes and thereby limit their extension.

Concerning the empirical scope of terrorism databases, HCTB only includes bomb attacks, whereas START and RDWTI include other use of threat of violence. In contrast to START, which does not further specify the target of a terrorist attack, HCTB and RDWTI both include only attacks on civilians.

The empirical scope of the databases on genocides, politicides, and incidents of mass violence varies greatly. Some, such as the CSP list and Valentino's list of incidences of mass violence, have a global focus, whereas the GSP dataset focuses on single cases. The population of cases of mass violence, on the one hand, and of genocides and politicides, on the other, overlap but do not match. By introducing a fatality threshold, Valentino not only excludes some genocides and politicides as coded by Harff but also includes cases that do not meet Harff's criterion of the intention to destroy a specific group. In contrast, the CSP's coup d'état event dataset as well as Powell and Thyne both include all successful and failed coup attempts by national elites.

Conflict and Security Data

The choice of a specific conceptual approach has a large influence on the structure and content of the dataset (see Table 1). For example, COW's 'War' dataset (v.4.0) is not geographically restricted. The dataset differentiates nine different types of wars, which are subsumed under the four categories of inter-, extra-, intra-, and nonstate wars. Some conflict types are also coded regarding conflict parties, but neither conflict-years nor conflict intensities or measures are coded individually. COW's MID dataset (v.3.1) aggregates data on the level of single disputes or on the level of the 5602 dispute participants. In addition, its MIDA and MIDB datasets include also information on specific conflict measures and distinguish seven levels of conflict intensity. The MIDI and MIDIP datasets break down disputes into 512 dyads and contain information on 2119 conflict incidents.

The ACD (v.4-2012) by UCDP has a global scope. The conflict-years and conflicts are differentiated into minor armed conflicts (about two-thirds of all conflict-years) and wars. Furthermore, the data distinguish between different conflict dyads and dyad-years. While the ACD holds information on the type of incompatibility, the other two UCDP datasets – the 'Non-State Conflict Dataset' and the 'One-Sided Violence Dataset' – lack such information.

In contrast to COW and UCDP, the CSP's MEPV dataset (v.2010) includes information on societal effects of warfare, such as population dislocation, infrastructural and environmental damage, the effects on societal networks, and diminished quality of life, and thus goes beyond casualty figures in assessing conflict severity. These data are presented as an aggregated value on a 10-point scale representing the magnitude of an MEPV in an affected country in a given year. Furthermore, the dataset differentiates seven types of conflicts by combining the criteria of conflict constellation (civil-intrastate, ethnic-intrastate, or international) and the aim toward which violence is directed (violence, war, or independence).

The CONIAS country-year dataset (newest version: 2013) comprises data on inter-, intra-, and subnational conflicts. It differentiates two nonviolent and three violent levels of conflict intensity on a yearly basis and includes information on conflict items and types of actors involved. A disaggregated dataset encompasses spatially (i.e., subnational entities) and temporally (month-by-month) disaggregated information on the means and consequences of violent conflict measures for Asia

Table 1 List of conflict and security statistics

Database	*No. of observations*	*Observation period*
COW	654 Conflicts	1816–2007
MIDA	2332 Disputes	1816–2001
MIDB	5602 Disputes at participant level	1816–2001
MIDI/MIDIP	512 Dispute dyads	1993–2001
MIDI	2119 Conflict incidents	1993–2001
MIDIP	4805 Incidents at participant level	1993–2001
ACD	248 Conflicts (2061 conflict-years)	1946–2011
ACD	524 Dyads (2601 dyad-years)	1946–2011
Nonstate conflict dataset	419 Nonstate conflict dyads (646 dyad-years)	1989–2011
One-sided violence	713 Actor-years	1989–2011
MEPV	8244 Episode-years	1946–2008
MEPV	326 Episodes	1946–2012
MAR	1670 Antagonism-years (including conflicts, protests, rebellions, and repressions)	2004–06
CONIAS	985 Conflicts (15 400 conflict-years)	1945–2008
GED	24 381 Events	1989–2010
ACLED	>75 000 Events	1997–2012
GTD	1 04 000 Terrorist events	1970–2011
HCTB	852 Terrorist Events	1991–2012
RDWTI	36 000 Terrorism events	1972–2009
CIRI	6030 Country-years	1982–2010
PTS	6800 Country-years	1976–2011
Mass killing	30 Incidents of mass killings in civil war	1945–2000
CSP coup d'état events	807 Coups (Including attempts, plots, and allegations)	1946–2011
Powell and Thyne (2011)	457 Coups (Including attempts)	1950–2010

and Oceania (2000–09) and globally (2011–12). In addition, event datasets such as UCDP's GED and the ACLED by PRIO code information on single conflict events for limited periods of time and individual countries or regions.

START's GTD contains information on various forms of terrorist attacks (i.e., bombings, assassinations, and kidnappings), whereas HCTB and RDWTI list terrorist events and incidents of terrorism. The ITERATE project provides georeferenced data on transnational terrorist groups, their activities, and the environment in which they operate.

CIRI and PTS both include information on human rights violations in more than 6000 country-years, whereas the dataset on mass violence by Valentino (2004) includes all incidents of mass killings in the twentieth century. The State Failure Problem Set of CSP includes a list of episodes of genocides and politicides and provides an estimation of the annual number of deaths on an 11-point scale. In contrast, the Biographic Database by the Cambodian Genocide Program of GSP contains several thousand biographical records on members of the Khmer Rouge movement and its victims as well as georeferenced data on prisons, mass graves, and memorials. Comparable datasets exist for the genocides in Rwanda, East Timor, Guatemala, and Former Yugoslavia, although the quality and amount of data varies considerably. Finally, the coup d'état events data by CSP includes data on coup leaders and outcomes for 804 successful, attempted, plotted, and alleged coups in the world, whereas the data provided by Powell and Thyne differentiate only between successful and failed coup attempts but exclude plotted or alleged coup d'états.

Contemporary Trends

There are three discernible trends in contemporary conflict and security statistics: an increased focus on individuals and societal groups (individualization), a broader understanding of the conflicts studied (extension), and better spatial and temporal resolution of conflicts (disaggregation).

Individualization

Since the early 1990s, researchers have noted that conflicts within states, and often without direct state participation, are the predominant form of violent disputes in the contemporary world. This has rekindled the interest in the social structures 'beneath' the visible surface of states. This development has been accompanied by a conceptual shift away from a traditional understanding of (military and state) security to a perspective focusing on the security of individuals and groups of individuals ('human security'). As expressed, e.g., in the 1994 Human Development Report of the United Nations Development Programme, the extensiveness of the concept of 'human security' – including 'freedom from fear' and 'freedom from want' – is specified by means of seven dimensions, namely, economic, food, health, personal-physical, cultural, and political security.

Apart from the political, legal, and academic debates that ensued in the wake of this paradigmatic shift (with keywords like 'responsibility to protect' and 'humanitarian intervention') and notwithstanding criticism of the concept of human security as a possible case of conceptual stretching, the new framework induced a quantitative approach to security in the form of the Human Development Index (HDI). While the HDI includes statistics of life expectancy, duration of education and a country's gross national income per capita to provide a ranking of currently 188 countries and territories, the Happy Planet Index (HPI), which was launched by the London-based New Economics Foundation, combines data on life expectancy with life satisfaction and the ecological footprint produced by attaining a certain level of well-being. However, neither the HDI nor the HPI include data on violent conflicts or political repression. However, this is done by the Human Security Index, which includes the Global Peace Index (GPI) and PTS.

Extension

The apparent surge of intrastate conflicts since the end of the Cold War also contributed to a better recognition of the role of nonstate actors in conflicts, especially in conflicts that are less intense than wars ('low-intensity conflicts'). The category of nonstate actors primarily includes armed groups, and also political parties, civil society groups, and the private sector. Armed groups involved in political conflicts may include rebel militias, terrorist groups, paramilitary forces, and private security companies. Furthermore, with the (ostensible) transformation of conflicts and the trend from classical warfare toward 'new wars' and terrorist strategies in the 1990s, many researchers have recognized that wars (and especially civil wars) often do not end with peace treaties or apparent victories. Rather, many conflicts resurface, sometimes repeatedly. In order to map such protracted and oscillating conflict dynamics, it is necessary to cover interwar phases of lesser conflict intensity, as well. In addition, conflicts of high intensity do not appear suddenly but typically undergo antecedent low-level violent and nonviolent stages. Moreover, different types of conflict often occur together with, or consecutive to, other conflict types, e.g., civil war and genocide, repression and revolutions, or subnational conflicts and terrorism.

Research institutions reflected upon these developments by devising more dynamic conflict concepts and extending their empirical scope. Within the framework of COW, the MID dataset was compiled in the beginning of the last decade, which also takes into consideration threats of the use of violence in international conflicts. In 2004, UCDP introduced the additional threshold of 25 battle-related fatalities to define 'minor armed conflicts' in contrast to wars. UCDP's GED dataset further lowered the threshold to one fatality. From its inception, the HIIK covered low-level violent and nonviolent conflicts and conflict phases, employing qualitative assessments to classify conflicts on a four-level scale. Since 2003, the HIIK and later CONIAS have used a five-level scale differentiating between entirely nonviolent disputes, conflicts that make use of threats of violence, low-level violent conflicts, limited wars, and full-fledged wars.

Disaggregation

In contrast to traditional conflict and security statistics, which focused exclusively on the national and international levels of conflicts on a year-by-year base, another recent trend in the research field has been to open the 'black box' of the nation-state by localizing conflicts within the geographical space of

a country. Research on geographical causes of conflict – especially the location of natural resources in a territory – demonstrated the need for a disaggregated form of geographical referencing. Furthermore, due to the increased emphasis on conflict dynamics, the trend has been to disaggregate conflict processes over time into basic units of 'events,' like individual battles or attacks. This development thus continues the conflict event research as represented by, e.g., the Kansas Event Data System, whose roots reach back to the 1970s (Schrodt and Hall, 2006), and Arthur S. Bank's Cross-National Time-Series Data Archive, launched in 1968.

UCDP's GED and PRIO's ACLED datasets combine both trends; here, events form the basis of georeferenced coding. In addition, GED construes geometrically defined conflict areas from the location of the coded events. While GED offers georeferenced data for the African continent for the period from 1989 to 2010, ACLED provides such data for Africa and selected Asian countries (1997–2012). The Event Data on Armed Conflict and Security Project in Berlin has also collected spatially and temporally disaggregated data concerning the use of violence in civil wars in four African countries in the period 1990–2009. In contrast to event data compilation, CONIAS has undertaken a georeferenced coding of intensities since 2011, i.e., of the severity of a given conflict in an administrative unit in a given calendar month, for the region of Asia and Oceania (2000–09). The intensity assessment is based on the violent and nonviolent actions of the conflict participants and is therefore conceptually related to the event-based approach.

In addition to these efforts, the spatial coding of factors relevant to political conflicts was aspired in recent years. In 2005 and 2007, respectively, PRIO published georeferenced information on the location of diamond resources and petroleum fields. In 2010, the International Conflict Research (ICR) group at the ETH Zürich released a dataset on the georeferencing of ethnic groups, containing a total of 929 ethnic groups. In the following year, the ICR published a georeferenced coding of settlement patterns of selected ethnic groups, the Geo-referencing Ethnic Power Relations dataset.

The Role of Conflict and Security Statistics in Research

Conflict and security statistics are primarily employed in research on the causes, dynamics, and structures of political conflicts. In addition, these statistics are relevant for the measurement of political regimes and political fragility as well as for early warning of political conflict and benchmarking of development aid policies.

The most widely used dataset for analyzing the patterns of intranational conflicts are published by UCDP and PRIO. Of central importance are also the datasets by COW, MAR, PITF, as well as by Fearon and Laitin. While some articles refer to the original data, many add self-compiled data to suit their specific explanatory focus. This may be a hint to deficits regarding the main databases on political conflicts as they apparently do not always satisfy the needs of researchers. However, the existence of a multitude of datasets enables robustness tests. In fact, some research articles employ more than one dataset in statistically assessing their hypotheses.

Conflict data are also relevant in regime measurements. For example, indictors of CSP's Polity IV dataset are inherently related to conflict. If conflict leads to a *de facto* separation of countries, this is coded as Polity Fragmentation. Periods where external intervention leads to the occupation of a country or where internal or international conflict triggers the collapse of a political regime are coded as Interruption or Interregnum Periods. Furthermore, internal unrest may lead to the coding of factional competition.

Evaluating political regimes is also associated with the measurement of state fragility. The UCDP dataset has been used by the Country Indicators for Foreign Policy Fragility Index, the GPI, the Harvard Kennedy School Index of African Governance, and the Peace and Conflict Instability Ledger (PCIL). The latter also includes data from the COW dataset. PITF data has been used by PCIL and the Index of State Weakness in the Developing World. CSP's MEPV dataset has been used by CSP's State Fragility Index.

In addition, conflict and security statistics are employed in Early Warning Systems (EWS) that aim at predicting the probability of the occurrence or escalation of violent conflict. Most EWS at least partly rely on or provide quantitative data that are linked to conflict and security statistics. However, as the occurrence of political conflict is the explanandum of EWS, conflict statistics are mostly not employed as explanans due to endogeneity problems, but are rather employed to optimize and test predictive models or as predictors for the escalation of ongoing conflicts of low intensity. In a similar fashion as in EWS, conflict statistics can also be employed in the evaluation of developmental aid. Geographical information on foreign aid projects and violent conflict allow assessing the impact of the former on the latter.

Challenges

Contemporary conflict and security statistics face challenges (1) in the geographical, temporal, conceptual, and material extension of data disaggregation; (2) the collaboration of research institutions; and (3) regarding availability and the reliability of conflict data.

While the disaggregation of conflict and security statistics has made considerable progress in recent years, the coverage of available georeferenced data on conflict events is largely limited to Africa and parts of Asia and the post-Cold War period. Moreover, efforts to disaggregate conflict events mostly focus on conflict measures, whereas conflict actors and conflict items have attracted far less attention. In addition, data on conflicts and conflict periods of no or very low violence, which would be necessary to develop a more adequate understanding of the dynamics of the emergence of conflicts as well as their termination, are mostly lacking. So far, only MID (for international conflicts), MAR (for protests and repression), and CONIAS (for all conflict types) include nonviolent conflicts. A further challenge lies in finding alternatives to the predominant measurement of conflict intensities in terms of battle-related deaths. A comprehensive assessment of the instruments and consequences of violent conflict would have to encompass the use and type of weaponry, the numbers and sociodemographics of persons involved, coverage of fatalities

from indirect consequences, data on displacement, the destruction of the environment or public infrastructure, and the availability of basic goods. MAR and CONIAS have taken steps in this direction. The disaggregation of conflict data may enable researchers to assess conflict dynamics more precisely than ever before, but analyses have to rely on data of explanatory variables that mostly are not yet available on the same level of precision.

Another challenge is the limited connectivity between different conflict datasets. This has resulted in a fragmented picture of the global conflict panorama and to a 'binning' of collected information in separate datasets. So far, only COW and UCDP have made considerable efforts to link their different datasets to each other internally. Externally, the challenge is partly addressed by attempts to interlink data banks of different institutions via shared identification numbers. However, integrating the wealth of information on conflicts into a comprehensive data bank still remains a largely unaccomplished goal. Most progress in this regard has been attained by ICR in Zürich, which hosts the GROW^{up} Research Front-End, integrating data on intranational conflict and ethnic groups. One source of the project is the ACD2EPR Docking Version 1.2 dataset, which links ACD v.4-2010 to the ETH Ethnic Power Relations (EPR-ETH) dataset v.2.0.

Finally, the availability and the reliability of information also pose challenges for the collection and procession of conflict and security data. The more disaggregated the measuring of conflicts is – geographically, temporally, and (as in the case of conflict intensity) conceptually – the more demanding the required information is. However, the quality and availability of information required is especially challenging in those regions affected by (violent) conflict. In addition, the growth of information technology, which has made information more easily available, has created new challenges of data processing. In this regard, a possible solution may be automated data gathering. One example is the Penn State Event Data Project, which covers political events in the Middle East, Balkans, and West Africa. Using information from the public domain such as international and local media reports may create reliability problems as it can be biased, e.g., by attention gaps, state censorship, or attempts of nonstate actors to influence media coverage for their own cause. This challenge can only be overcome by systematically evaluating the sources employed and by training the data collectors in country-specific knowledge. In contrast, attempts by conflict researchers to compensate these challenges by employing personnel in the field should be regarded with caution. Access to events on the ground is frequently restricted, while any direct observation might exacerbate the researcher's problem of objectivity.

Abstract

As a rule, core databases contain quantitative survey data. Traditionally, qualitative data, for example, ethnographic field notes or transcripts of group discussions and interviews, have not been made available for secondary analysis. This is slowly changing, and a number of data archives in Europe, Australia, and the US are working on the archiving of qualitative data. Quantitative social science datasets are usually generated by major surveys, such as general social surveys, household panel studies, thematic surveys, or barometer studies, and made available for analysis.

Methodological Characteristics of Quantitative Surveys

Sampling Techniques

Quantitative surveys are characterized by the fact that they employ a standardized questionnaire that is administered to a group of individuals (subpopulation) selected from the total population being investigated (target population, survey population). Respondents are selected from the target population using a random statistical sampling procedure (Kish, 1994). It must be ensured that each individual in the target population has a chance (greater than zero) of being selected.

Surveys are used to measure demographic, socioeconomic, attitudinal, and behavioral characteristics. With the help of these data, conclusions can be drawn about the attitudes, opinions, and behavior of all the social groups in the sample – and, therefore, in the target population – under the conditions specified in the survey questions. Surveys help researchers to observe society. Because major surveys are repeated at regular intervals, and despite the fact that very few of them have access to the same respondents each time, they provide not only a thematic snapshot but also an insight into attitudinal and behavioral changes in society over time. This is due to the fact that random sampling techniques enable each sample to be drawn under the same conditions and from the same target population so that the subpopulation displays the same structural characteristics each time. The aim of a standardized survey with a random sample is to construct quantitative descriptors of the characteristics of the target population from which the sample is drawn (cf Groves et al., 2004: p. 2).

Methodologies

Once the sample has been drawn, the design of the questions and the questionnaire can begin. Here, the methodological focus lies on choosing a survey method (face-to-face, telephone, mail, etc.), formulating the survey questions, and pretesting the questionnaire. Special methods are used when formulating and structuring questions and response categories in order to reduce response errors (Krosnick and Presser, 2010: p. 263).

First, researchers must familiarize themselves with the cognitive processes underlying responses to survey questions (Schwarz, 2008: p. 374). Bearing this knowledge in mind, they can then begin to formulate the questions and the response categories. Because respondents constitute a heterogeneous group that differs in terms of age cohort, social class, and regional and cultural origins, the wording of questions and response categories must be specific, concrete, and easy to understand (Converse and Presser, 1986: pp. 10, 31; Krosnick and Fabrigar, 2006).

The datasets presented here undergo further processing by the institution that makes them available for secondary analysis, which is the reanalysis of data collected in a survey. While this institution may be the research body on whose behalf the data were collected, more often than not it is an archive for social science datasets. In contrast to a team of researchers that processes its own data and makes them available to others, data archives are experienced in processing data, preparing user-friendly tools for secondary analysis, and ensuring secure, long-term preservation of data. Moreover, major data archives have an international network.

Types of Core National Datasets

A look at the core national datasets generated by surveys and made available for secondary analysis reveals five types of surveys:

1. General social surveys (GSS) conducted at regular intervals. The data from these surveys are made available for research and teaching purposes.
2. Household panel surveys, normally conducted as follow-up surveys, whose main objective is to study the economic and social structure of private households and to monitor and measure changes over time.
3. Longitudinal education surveys (some of which are trend studies, others are panel studies), meaning follow-up surveys that focus on students' competencies and conditions for teaching and learning, as well as passages within the national education system and transitions from the education system to the labor market.
4. Thematic specialized social science surveys that can be regarded either as individual snapshots or as a series of snapshots of a specific theme.

5. And finally, cross-national barometer surveys conducted with more or less standardized questionnaires that furnish an insight into the attitudes, opinions, and behavior of the target populations in the participating countries.

General Social Surveys

GSS are academically driven national surveys carried out at regular intervals. 'Regular' means that the next wave of the survey is conducted 1 or 2 years later. As a rule, the target population comprises all persons of 15, 16, 18 years of age and above, who are residents in private households. An upper age limit is not common. In most countries, the sample is a random one (also known as a probability sample). The questionnaire comprises a standard core of socio-demographic, behavioral, and attitudinal variables collected in each wave, and a topical module that varies from wave to wave. The replicating core enables social developments to be studied over time, thus facilitating time-trend studies. The topical module often focuses on several issues of topical interest. In each country, a renowned national social science institute or a university-affiliated research institute is usually given responsibility for conducting the GSS. However, as the examples from the Australian, New Zealand, and Canadian GSS show, academically driven surveys are not always conducted by an academic research institute or a university. In these three countries, responsibility for the major national surveys lies with the national statistical institute (NSI).

After data collection and processing, datasets are made available for general use. Social science institutes and universities, in particular, employ the data for teaching and research purposes. Because the datasets are often available online, the secondary analysis of the GSS data is not restricted to researchers in the country in question.

The most prominent GSS is the *US General Social Survey*, which has been carried out since 1972 by the National Opinion Research Center (NORC) at the University of Chicago. Although it was conducted annually at first, the US GSS has employed a biennial design since 1994. In 2006, it began the transition from a replicating cross-sectional design – that is, a new sample was drawn for each wave – to a design that uses rotating panels. This rotating panel design means that, in the ideal case, the GSS is administered to each respondent for three successive waves. After three waves, the respondent is replaced by a new recruit. Eventually, about one-third of the panel is replaced after each wave. The advantage of a rotating panel design is that it facilitates the modeling of attitudinal and behavioral changes across three waves. Three waves are the prerequisite for structural equation modeling. Longer participation in the panel is detrimental to the respondent's spontaneity when answering the questions.

What is interesting about the US GSS is that, from its inception, it has not only been a source of data, but has also contributed to survey methodology (Smith, 1979: p. 11). The fact that NORC has fulfilled its mandate in this regard is evidenced by the reports on various aspects of survey methodology to be found on the US GSS Web site (US GSS, 2013).

The idea for, and the concept of, the US GSS has been taken up in numerous countries, for example, Germany, Poland, Russia, Australia, New Zealand, and Canada. As a result, the national GSS is deemed to be the best source of data with which to observe national attitudinal and behavioral trends.

ALLBUS (ALLgemeine BevölkerungsUmfrage der Sozialwissenschaften), the *German General Social Survey* (ALLBUS, 2013), was implemented for the first time in 1980. In 1984, collaboration between the organizers of the GSS in four countries (Germany, the USA, the UK, and Australia) yielded the *International Social Survey Programme* (ISSP) (ISSP, 2013). Fielded for the first time in six countries in 1985 as a supplement to the regular GSS, the ISSP is now conducted annually in 48 countries (as of 2012) either as a supplement to the GSS or another national survey, or as a survey in its own right. To date, 11 topics have been covered by the ISSP, most of which are repeated at regular, but unequal, intervals.

The year 2003 saw the inception of the *Chinese General Social Survey* (China GSS, 2013), which is conducted annually or biennially with different focal themes. The China GSS is based on a stratified random sample representative of the urban and rural population (above 18 years of age). Datasets are not only freely accessible for research and teaching in China, but may also be used by researchers outside China. Hence, the survey provides a valuable opportunity to obtain information about social structure and trends in China.

Selected Household Panel Studies of Income and Living Conditions

Defining Panel Studies

Panel studies are longitudinal surveys that use the same units of observation each time. The advantage of longitudinal (panel) surveys is that they enable researchers to measure and analyze changes over time in socio-demographic and economic situations, as well as the attitudes, opinions, and behaviors of individuals or aggregates of individuals. The unit of observation of household-based panels is the household and its members. Household panels enable researchers to study household change and the changing dynamics of the individuals within the household (cf Stafford, 2010: pp. 765 ff.).

Examples of National Panel Studies

The US *Panel Study of Income Dynamics* is "the world's longest running nationally representative household panel survey" (PSID, 2013). It started in 1968 with a panel of 18 000 individuals living in 5000 families in the US. The panel has since grown to 22 000 individuals living in over 9000 families. Interviews were conducted annually until 1997. Since the 1999 wave a biennial design has been used. Over the years, the panel has been expanded to reflect post-1968 immigration.

Established in 1993, the *Survey of Labour and Income Dynamics* (SLID) is a longitudinal annual household survey conducted by Statistics Canada. SLID comprises two panels, each of which includes some 34 000 individuals living in 17 000 households. "A panel is surveyed for a period of six consecutive years. A new panel is introduced every 3 years, so two panels always overlap" (SLID, 2013). The target population is all individuals resident in private households in Canada with the exception of residents of the Yukon, the Northwest Territories and Nunavut, and persons living on Indian reserves.

The *British Household Panel Survey* (BHPS) started in 1991 with a panel of some 9092 individuals living in 5050 households throughout Great Britain. The panel was topped up for the ninth wave in 1999 by adding two samples of 1500 households each from Scotland and Wales. For the eleventh wave in 2001, 1900 households from the Northern Ireland Household Panel survey were integrated into the BHPS, thereby making it suitable for UK-wide research (BHPS, 2013). The BHPS was conducted annually until 2008. In 2009, it was incorporated into *Understanding Society*, the UK Household Longitudinal Study (Understanding Society, 2013). Understanding Society covers around 40 000 households in England, Scotland, and Wales and 2400 addresses in Northern Ireland. Interviews are repeated annually; the data are available from the Economic and Social Data Service (ESDS, 2013).

The *DNB Household Survey*, formerly known as the CentER Savings Survey, is a Dutch panel survey that studies the psychological and economic aspects of financial behavior (DHS, 2013).

The *Longitudinal Internet Studies for the Social Sciences* (LISS) panel comprises some 8000 individuals living in 5000 households in the Netherlands. LISS began in 2007; it was supplemented with a separate immigrant panel of 2400 individuals living in 1600 households in 2010 (LISS, 2013).

The *Longitudinal Individual Database* (LINDA) is a register-based Swedish household panel that was established in 1960. A nonoverlapping immigrant sample with the same design and covering the same time period as the main sample is attached to LINDA. LINDA stores annual information of about 300 000 individuals. "The core of the data is the annual income registers (Inkomst- och taxeringsstatistiken) and population census data (Folk- och Bostadsräkningen) available every fifth year from 1960 to 1990" (LINDA, 2013). All the variables in these registers are included in the LINDA database. Researchers can access the data through Statistics Sweden.

First implemented in 1984, the *Socio-Economic Panel Study* (SOEP) is a panel survey of private households in Germany. Some 20 000 individuals living in 11 000 households are surveyed annually (SOEP, 2013). The first wave covered 12 245 individuals living in 5921 households. In 1990, after German reunification, 2179 households with 4453 members from the former German Democratic Republic were added to the panel. In 1994, the panel was topped up once again by adding a sample of 1078 immigrants, or persons with a migrant background, living in 522 households. Supplementary samples added in 1998, 2000, 2002, and 2006 ensure that SOEP is representative of the German population as a whole and facilitate more detailed analyses of specific subgroups.

The *Swiss Household Panel* (SHP) is an annual panel study established in 1999 to "observe social change, in particular the dynamics of changing living conditions and representations in the population of Switzerland" (SHP, 2013). The SHP started with a sample of 12 931 individuals living in 5074 households. In 2004 a second sample of 2538 households with a total of 6569 household members was added. A biographical questionnaire aimed at collecting retrospective data on professional development and family life was administered in 2002.

The *Panel Socio-Economique "Liewen zu Letzeburg"* (PSELL) began in 1985 with 6110 individuals living in 2012 households in Luxembourg. In 1995 the original panel was replaced by a new household sample, PSELL2. PSELL3, which started in 2003 with 3500 households, is the Luxembourg component of the European Survey on Income and Living Conditions (EU-SILC).

The *Russia Longitudinal Monitoring Survey* (RLMS) is a household-based panel study launched in 1992. To date, 20 rounds have been conducted. Individual household members who moved away from the address are not followed. In each annual round, the RLMS interview is completed with the household and its members at the original sample dwelling unit (RLMS, 2013). Consequently, the RLMS is not a true household or person panel, but a panel of dwelling units.

The following is a list of further national household panel studies:

- The *Panel Study of Belgian Households* started in 1992. In 2003, it was transformed into the Belgian component of the EU-SILC.
- The *Household, Income and Labour Dynamics in Australia* (HILDA) survey started in 2001 with a panel of 19 914 individuals in 7682 households. In the eleventh wave, a sample of 5477 individuals in 2153 households was added to the panel (HILDA, 2013).
- The *Survey of Family, Income, and Employment* (SoFIE) is a New Zealand panel survey conducted annually between 2002 and 2010.
- The *Mexican Family Life Survey* was first implemented in 2002. The second wave took place in 2005–06 (MxFLS, 2013).
- The *Korean Labor & Income Panel Study* (KLIPS) is an annual survey of households and individuals residing in urban areas. Conducted by the Korea Labor Institute, the first wave was launched in 1998 (KLIPS, 2013).
- The *Hungarian Household Panel Study* (HHP) was a sample of 2600 households surveyed annually between 1991 and 1997.
- The *Bosnia and Herzegovina Household Survey Panel Series – Living in BiH* started in 2001 with over 3000 households. The last wave was implemented in 2004 (LiBiH, 2013).

European-Wide Panel Studies

In 1994, the European Union launched its first panel survey, the European Community Household Panel (ECHP). All member states were obliged to participate.

The ECHP survey was based on a standardized and input-harmonized questionnaire that involved annual interviewing of a representative panel of households and individuals in each member state. In the first wave, carried out in 1994, a sample of some 60 500 nationally represented households with approximately 130 000 adults of 16 years of age and above were interviewed in the 12 member states. Austria and Finland joined the project in 1995 and 1996, respectively. From 1997 onwards, new member Sweden provided data derived from the Swedish Living Conditions Survey. The total duration of the ECHP was 8 years, running from 1994 to 2001 (ECHP, 2013a). Access to the anonymized microdata is provided only by means of research contracts and is restricted in principle to universities, research institutes, NSIs, central banks inside the EU and EEA countries, as well as to the European Central Bank (ECHP,

2013b). The ECHP was discontinued in 2001 and was succeeded by the EU-SILC survey.

The EU-SILC survey was formally launched in 2004 and expanded in 2005 to cover all the 25 member states of the EU. Since 2007, a total of 31 countries – the EU-27 member states together with Norway, Iceland, Switzerland, and Turkey – participate in the survey (EU-SILC, 2013a). Access to EU-SILC microdata is subject to the same restrictions as access to ECHP data (EU-SILC, 2013b).

Education Surveys

International Education Surveys

The most well-known education survey is the OECD *Programme for International Student Assessment* (PISA), which assesses 15-year-old students' competencies in reading, mathematics, and science. The first survey was conducted in 2000 in all OECD member countries and a number of partner countries. Subsequent PISA surveys have followed at 3-year intervals (PISA, 2013). Although PISA is a cross-national comparative survey, it focuses on the weaknesses of students in the individual member countries. By contrast, the focus of the OECD's *Teaching and Learning International Survey* is on the analysis of teaching and learning environments in schools (TALIS, 2013). These education surveys are supplemented by the OECD *Programme for the International Assessment of Adult Competencies* (PIAAC). The first PIAAC survey was conducted in 2011–12, and preliminary results are expected in 2013. PIAAC builds on the OECD's *Adult Literacy and Life Skills Survey*, which was conducted in two main waves between 2002 and 2008, and the *International Adult Literacy Survey* undertaken in three rounds between 1994 and 1998 (PIAAC, 2013).

Developed and conducted by the International Association for the Evaluation of Educational Achievement (IEA), the *Trends in International Mathematics and Science Study* is an international assessment of fourth and eighth grade students' achievements in mathematics and science. First implemented in 1995, it has been carried out every 4 years since then. In 2011, 69 countries participated in the study (TIMSS, 2013).

The *Progress in International Reading Literacy Study* (PIRLS) is also conducted by the IEA. PIRLS measures fourth grade students' reading literacy achievement. First conducted in 2001, it was repeated in 2006 and 2011. The IEA plans to continue testing literacy achievement every 5 years. The data from 2011 are available for 49 countries (PIRLS, 2013).

National Education Surveys

In addition to these international surveys, there are national education studies that provide descriptive data on the educational activities of the national population and conditions of teaching and learning in schools. These studies include, for example, the US *National Household Education Surveys Program*, which provides descriptive data on the educational activities of the US population (NHES, 2013). This study is supplemented by the *Teaching, Empowering, Leading and Learning* surveys that examine conditions of teaching in all the US federal states. In the UK, the *Adult Participation in Learning Surveys* have been measuring adult participation in learning since 1996. The *All India Educational Survey* (AIES), which was implemented for the first time in 1957 and has been conducted at (ir)regular intervals since then, collects information on the various aspects of school education and infrastructure that education planners and administrators require in order to improve conditions for teaching and learning. The eighth AIES was conducted in 2009 (AIES, 2013).

Educational panel studies, such as the *German National Educational Panel Study*, collect longitudinal data on the development of competencies, educational processes, educational decisions, and returns to education in formal, nonformal, and/or informal educational institutions. This facilitates the analysis of educational and training processes throughout the life span.

Transitions from education to employment surveys, for example the *Transitions from Education to Employment* survey in Switzerland and the Canadian *Youth in Transition Survey*, observe the trajectories of school leavers from the educational system to the labor market.

Thematic Social Science Surveys

The Importance of National Archives and Statistical Institutes

The archives for social science data are well stocked with individual thematic social science surveys. Of most interest to social scientists are surveys that are of relevance to their own research questions. Hence, when searching for national manifestations of specific social phenomena, it is worth taking a look at the archives. Their offerings include, for example, national and cross-national comparative surveys on topics such as the labor market, criminality, victimization, and health. These studies range from very specific individual surveys to national or regional surveys that are repeated at regular intervals.

The main individual thematic social science surveys are those conducted by NSIs. The value of these surveys lies in the fact that they are conducted regularly and thereby facilitate the analysis of societal trends. Moreover, to the extent that they are generated in the member countries of the EU, many of these datasets must be submitted to the Statistical Office of the European Union (Eurostat). This means that, in addition to the analysis of national trends, there is the added value of cross-national comparison – at least within the EU.

Labor-Related Surveys

Of interest in this connection is the *Labour Force Survey* (LFS), "a standard household-based survey of work-related statistics" conducted in 200 countries and territories worldwide (ILO INFORM, 2013). The underlying concept of the survey was developed by the International Labour Organization (see ILO, 1982). The LFS employment, labor market, and working conditions data serve to determine the economic potential of the society in question. Since 1992, the LFS is supposed to be implemented on an annual basis. However, in 1998 the Council of the European Union adopted a regulation ruling that the LFS was to be conducted by the EU member states as "a continuous survey providing quarterly and annual results" (Council of the European Union, 1998: p. 3). The quarterly results provide an insight into seasonal fluctuations on the national labor markets.

In addition to measuring respondents' demographic background, data are collected on the following topics: labor status,

employment characteristics of the main job and the second job, visible underemployment, search for employment, education and training, previous work experience of persons not in employment, main labor status, and income (The Council of the European Union, 1998: pp. 4 f.).

Crime and Victimization Surveys

Crime and victimization are topics that are well represented in national surveys as evidenced by the growing number of *crime surveys*, *crime and safety surveys*, and *crime and victimization (victim) surveys*. As the United Nations Office on Drugs and Crime notes: "While in the past only police and criminal justice data were used to measure crime, it is now widely acknowledged that such information alone is not sufficient and should be integrated with victim surveys results" (UNODC, 2013). Irrespective of which of the three labels they bear, these surveys can be found in numerous countries – not only in North America, Europe, Australia, and New Zealand but also in countries such as South Africa and Nigeria. Their primary aim is to study the national situation.

Because some of these surveys have been conducted on a regular basis for several decades, they are a valuable resource when it comes to monitoring trends and identifying changes over time. Examples of such long-standing surveys include the annual *National Crime Victimization Survey*, which has been conducted by the US Census Bureau on behalf of the Bureau of Justice Statistics since 1973 (approx. 75 000 respondents in 2011) and the *British Crime Survey*, which was first implemented in 1982 and has been conducted annually since 2000 (approximately 50 000 respondents in 2011). Even though the questionnaires employed by national surveys are not cross-nationally harmonized, cross-national comparisons are still possible. Comparability is enhanced by the fact that in 1984 the United Nations decided to build a database of crime and victimization survey data. This led to the initiation of the *International Crime Victim Survey* (ICVS) by a group of European criminologists (Van Dijk et al., 1990). The survey has been conducted in some 80 countries since 1989 using a standardized questionnaire and methodology (UNODC, 2013). A consortium of commercial and academic research institutes cofinanced by the European Commission is now responsible for the execution of the ICVS in the member states of the EU. The EU version of the ICVS, the *European Crime and Safety Survey*, was implemented for the first time in 2005 in 18 EU member states using an instrument and methodology based on that of the ICVS (EU-ICS, 2013).

In recent years, crime and safety surveys have been supplemented by economic crime surveys. At present, one main focus of these surveys is cybercrime.

Health-Related Surveys

Health is another important topic of social science surveys. The first *health surveys* go back to the 1950s. Here, too, in addition to once-off surveys, a large number of countries employ a replicating cross-sectional design in order to monitor trends in the health status and behavior of the population (persons living in private households). The health surveys differ from other surveys in that, in some cases, the target population is not the resident population as a whole but rather specific subgroups within the resident population, selected on the basis of age or sex. Moreover, the territorial hierarchy of the investigation areas can range from the world (*WHO World Health Survey*), through national states, to regions, whereby a region can be a federal state, as in the case of the USA or Australia, a province, a district, or even a metropolitan area (for example, the *New York City Community Health Survey*).

The health surveys employ a random sample drawn from the specified target population and a standardized questionnaire. Interviews are frequently supplemented with rudimentary medical examinations entailing the measurement of weight, height, and blood pressure. Some studies also take blood and urine samples. However, datasets from studies of this kind are found less in social science archives than in those, often public, research institutions under whose aegis the survey is conducted. Many of these datasets are classified as public use files and are accessible for research purposes.

Barometer Surveys

Another category of social science survey is the barometer survey. Barometer surveys are cross-sectional surveys of national population samples that are repeated at regular intervals. In addition to socio-demographic variables, these surveys measure respondents' attitudes to the social, economic, and political situation in the country in question. With the exception of Oceania, barometer surveys are conducted on all continents, although they are sometimes limited to metropolitan areas. The following is a brief introduction to the main barometer surveys:

The Eurobarometer

Eurobarometer (EB) is a series of surveys conducted on a regular basis on behalf of the European Commission in all EU member states and the candidate countries (EB, 2013). The aim of the EB program is to monitor the evolution of public opinion in the member states and the candidate countries. Apart from questions about topical issues, respondents are asked for their opinions on topics such as European unification, the social situation of minorities, health, culture, and environmental protection.

The main EB survey is the *Standard EB*. First implemented in 1973, it is now fielded biannually. The Standard EB is supplemented by surveys such as the *Special EB* and the *Flash EB*. The Special EB comprises in-depth thematic studies conducted on behalf of EU institutions on topics such as the European elections (2009) or climate change (2011). The survey data serve as a basis for decision making on the part of the institution in question. The Flash EB are ad hoc thematical telephone surveys aimed at quickly gauging public reaction to current events. Between 2001 and 2004, separate surveys – the *Candidate Countries Eurobarometer* (CCEB), the methodology of which was almost identical to the Standard EB – were conducted in the 13 countries that joined the EU between 2004 and 2007, and in Turkey. The objective of these surveys was to gauge public opinion on European integration and EU institutions and policies. The CCEB replaced the *Central and Eastern*

EB. On the one hand, the EB surveys are a political instrument commissioned by political institutions. On the other hand, however, they yield a wealth of data on the development of living conditions and the attitudes of the citizens of current and potential EU member states, data that are of great interest to social researchers.

The Afrobarometer

The *Afrobarometer* "is an independent, nonpartisan research project that measures the social, political, and economic atmosphere in Africa" (Afrobarometer, 2013). The first Afrobarometer was conducted in 1999 in 12 sub-Saharan African countries. Round 5, conducted by public and private research institutes, got underway in 22 countries north and south of the Sahara in 2011, and data collection was still ongoing in some countries at the time of going to press (2013). It is expected that up to 35 countries will participate. The survey is methodologically well documented and the data are freely available online via the Afrobarometer Web site. Respondents are asked to assess both their own economic and living conditions and the economic and living conditions in the country as a whole. Although a standardized questionnaire is used in all participating countries, the data are more useful for the analysis of the respective national situation than for cross-national comparison purposes.

The Latinobarometer

First fielded in 1995, the *Latinobarómetro* is an annual survey conducted in up to 20 Latin American countries. Between 1000 and 1200 respondents are interviewed in each participating country. The Latinobarómetro focuses on social, economic, and political development. Topics covered include democracy, institutions, law and constitution, politics, political parties, participation, corruption, discrimination, poverty, international relations, trust between countries, values, communication media, social capital, the economy, and trade (Latinobarómetro, 2013).

The AmericasBarometer

The *AmericasBarometer* is conducted by the academic institution, Latin American Public Opinion Project (LAPOP), which is hosted by Vanderbilt University in Nashville, Tennessee. LAPOP began with the study of democratic values in Costa Rica in the 1970s. Between 1991 and 2005 it conducted 41 surveys in Latin American countries. The *AmericasBarometer* was established in 2004, with 11 countries participating in the first round. Since then it has been conducted biennially in a steadily growing number of countries in North, Central, and South America, and the Caribbean. The US, 24 Latin American countries, as well as Canada participated in the latest round, which took place in 2012. The survey focuses on "popular opinions toward the economy, tolerance, corruption, and support for democracy in the Americas" (AmericasBarometer, 2013).

The Asian Barometer Survey

Established in 2001, the *Asian Barometer Survey* (ABS) grew out of the *East Asia Barometer*. It is an "applied research program on public opinion, on political values, democracy, and governance around the region. The regional network encompasses research teams from 13 East Asian political systems, and 5 South Asian countries" (ABS, 2013). The main aim of the ABS is to gauge public opinion on political values, democracy, governance, human security, and economic reforms. The latest wave took place in 2011.

The Arab Democracy Barometer

The *Arab Democracy Barometer* was established in 2005. The second wave of the survey, which was conducted between 2010 and 2012 in eight Arab countries, sought to measure politically relevant attitudes of the resident populations. The organizers attached importance to being able to compare countries beset by political unrest with countries unaffected by such unrest. The second wave sought to measure "citizen attitudes, values, and behaviour patterns relating to pluralism, freedoms, tolerance and equal opportunity; social and inter-personal trust; social, religious and political identities; conceptions of governance and an understanding of democracy; and civic engagement and political participation" (Arab Democracy Barometer, 2013).

The New Democracies Barometer

The *New Democracies Barometer* (NDB) was established in 1991 by the Paul Lazarsfeld Society in Vienna. Between 1991 and 1998, surveys were conducted in 10 Central and Eastern European countries that had a socialist system until 1990 and were undergoing transformation at the time. The aim was to gauge the effect of the experience of democracy and markets on the attitudes and behavior of the people.

Conclusion

Large internationally accessible social science datasets help researchers to classify their own data and may also facilitate comparative analyses. The fact that more and more data holders are providing users with online access to their data and are making their analytical tools/programs freely available to the scientific community has considerably enhanced access to these datasets. The increasing cooperation between the data archives has also considerably enhanced the universal accessibility of their respective data.

However, comparability across datasets is hampered by the lack of standardization of demographic and socioeconomic variables. At present, datasets can be harmonized and compared only according to the sex, age, and education (in three broad and largely undefined categories) of the respondents. Therefore, in order to fully realize the analytical potential of survey data, generally accepted rules for the standardization of demographic and socioeconomic variables are called for.

Abstract

Interviews are fundamental tools in the social sciences for different styles of research such as experimental, survey, fieldwork, and nonreactive research. According to some theories of measurement, all measurement involves interaction (usually between two people), and interviews are particularly noteworthy in this respect. The article relates four theories of social interaction within the interview process: role theory, exchange theory, conflict theory, and symbolic interaction. It concludes by noting the necessity of a multimethod strategy to refine the use of interview techniques in social science research.

Interviewing is a process of social interaction in which a researcher questions subjects or respondents for the purpose of gaining information or data. Interviewing styles may range from informal conversations to semifocused topical interviews to more formal standardized questionnaires that reflect different degrees of control over the interview. As social interaction, interviewing may be analyzed by different theories of social interaction – specifically, role theory, conflict theory, exchange theory, and symbolic interaction. Each of these highlights different aspects of the interview that may introduce bias and affect the validity of the data. Research is presented that demonstrates the degree of bias introduced by race, class, gender, age, and various other aspects of the interview situation.

The social science interview is a situated social interaction, the purpose of which is to transfer information from one person to another. Information or data are obtained from one person, the respondent or subject, as he or she answers questions posed by another, the interviewer or researcher. The interview in its myriad forms is a primary data-gathering tool of social scientists, and therefore, it is important to understand the interview process, since this will affect the nature and quality of the data gathered or generated.

Situating the Interview

Interviews may be conducted in a variety of ways and in a variety of situations. Inevitably, they are socially and methodologically embedded in larger contexts (Kvale and Brinkmann, 2009). Relatively little research has been done either on the impact of different social situations and settings on the conduct of interviews or on the impact of varying situations on the reliability and validity of interview results. The social setting may range from the privacy of the home to the office to the public 'person on the street,' and the social context may range from a highly private, anonymous, or confidential one-on-one interview to one involving the presence of strangers or intimate family and friends as co-respondents. Research has shown that in contrast to the one-on-one interviewer–respondent situation, the presence of others tends to produce more socially normative responses (Lever, 1981). Much more research is needed on the impact of these varying social contexts.

We must also situate interviews in the different methodologies or styles of research used by social scientists. For heuristic purposes, we can identify four major styles of research: experimental, survey, fieldwork, and nonreactive research. The interview, though found in all the four methods, is particularly important in survey and field research, and these may be thought of generally as representing quantitatively verses qualitatively oriented interview styles, respectively. The quantitative–qualitative distinction itself encompasses a variety of comparisons that may range from more philosophical and epistemological issues such as objective verses subjective knowledge to more grounded and specific issues of questionnaire construction and closed verses open answer formats. A central distinction running throughout these comparisons is the question of the nature of control over the interview format and content.

A Note on Control over the Interview – Form and Content

Different interview formats may be arrayed on a number of different continua, but of particular significance is the question of varying degrees of control. At one extreme, the interviewer exerts full control over the situation, and at the other, the interviewer seemingly minimizes control, relinquishing more control over the situation to the respondent. There is a zero-sum quality of control in the relationship between interviewer and respondent. The case of maximal interviewer control is exemplified by the 'forced-choice' survey interview, where not only the format of the question is standardized (stimulus), but the possible answers of the respondent are standardized as well (response). The interviewer ensures a constancy of routinized control in order to generate highly reliable data. Concerns over such control are often associated with surveys where the interview is used as a tool to generate standardized data from a sample of numerous units for the purposes of aggregate analysis that may be generalized to some larger population.

The other extreme, where the interviewer exercises minimal control, is seen, for example, in the Rogerian psychoanalytic interview. Here the respondent is 'in control' as to the content of the interview and the interviewer is trained to be 'nonreactive.' It should be noted, however, that even here the

interviewer is exercising control over the format or form of the interview, and that both the forced-choice survey interview and the nonreactive interview (Rogers, 1945) are interaction situations far removed from the 'natural' form and content of everyday personal interaction. The field interview of participant observation is, by contrast, a situation often closer to the give-and-take of everyday 'normal conversation' (Seidman, 2013). The respondent exercises a degree of control over both the content and the form, but the interviewer, through judicious use of probes, can often guide the interview into topic areas of interest to the researcher. This is the case with the 'focused' or 'topical' interview (Merton, 1956). From these considerations, one may construct a typology of control that the researcher exercises in the interview situation:

typology of interviewer control in different styles of research interviews

	Control over content	
	Hi	Low
Hi	survey questionnaire Control over form	nondirective psychoanalytic
Low	semifocused in-depth	conversational fieldwork

These different interview formats are often associated with survey verses fieldwork, but extend to a variety of methods. A multimethod strategy that emphasizes different strengths and weaknesses of different methods or styles of research nonetheless values the interview as a central data collection tool that can simultaneously provide quantitative and qualitative data, and even be used in multimethod experimental strategies. For example, Schuman et al. (1985) incorporated an experimental design into a survey by having interviewers systematically vary the format of questions asked of different respondents.

The Theory of the Spring

Some have suggested that all measurement involves interaction (Babbie, 2013) – interaction with the external world in some form or another in order that information about that external world may be transferred to an observer. Theories of measurement take into account a detailed exposition of the measurement process itself as constitutive of the data generated. In the prosaic act of weighing a bunch of bananas in the produce section of a grocery store, for example, one is operating on an assumption about how the spring in the scale responds to varying masses of bananas subjected to the law of gravity in moving the dial in a consistent and credible way. One operates on the assumption that some scientist or engineer has worked out in detail the physical elasticity of the steel spring at the heart of the scale's measurement process. In the interview, this interaction is particularly noteworthy, since it is *social* interaction – usually between two people – and the corresponding theories of measurement most applicable are theories of social interaction itself. In this section, we will briefly apply four distinct theories of social interaction to the interview to see the varying perspectives they provide on this all-important data-gathering tool. The four theories of social interaction are (1) role theory, (2) exchange theory, (3) conflict theory, and (4) symbolic interaction.

Role Theory

Role theory begins with a set of normative expectations that are presumed to define particular positions or statuses in social structure and their corresponding roles or behaviors in interaction with others. The roles or statuses most clearly central here are those of 'interviewer' and 'respondent' themselves. How well one knows these roles, that is, knows the normative expectations for behavior associated with the respective roles, is a function of one's prior experience and knowledge gained either first hand or through vicarious observations – in the media, through cartoons, through conversations, or in the classroom. To be 'trained' as an interviewer is to learn a set of normative expectations about how one should interact with a respondent. The simplest norms are 10 of those that are 'taken for granted' such as who asks the questions and who gives the answers. Sometimes there are widely accepted norms defining the ideal interviewer role such as one should not reveal personal information that might thereby bias the respondent's responses (Gordon, 1975). However, even these commonplace, widely shared norms may come into question, as there may be conflict among the different goals for the interview. For example, one goal may be to get as much revelatory information as possible verses another goal to not bias the respondent's answers. The different goals of the interview (more fully revelatory data vs unbiased data) may come into conflict and suggest different contradictory norms, for example, about how much personal information the interviewer should reveal to the respondent in the interview situation.

Role theory asserts that the norms governing interaction are there for the purpose of realizing specified goals out of the interaction. In short, normative behavior is goal oriented. The norms governing the interviewer are likewise oriented to maximizing certain qualities (or values) of the data – for example, norms that call for a common stimulus to achieve validity across respondents or other norms that emphasize supportive interaction to produce full and complete responses.

A common application of role theory to the interview situation is a concern with bias introduced by other social statuses in a person's status set – the most obvious and frequently researched being the ascribed and highly visible social statuses of race, gender, and age. These statuses are often considered to be especially important when questions in the interview touch on topics closely related to them. Much research has been conducted on the effects of these statuses on interview outcomes precisely because they are considered to be master ascribed statuses that are both readily observed and ubiquitous in all interactions. They are often attributed even in telephone interviewing and not just in face-to-face situations.

One of the earliest findings of interviewer effects by race, dating to World War II, was that answers to questions about race relations were strongly impacted by the races of the interviewer and respondent (Hyman et al., 1954). African-Americans reported lower levels of satisfaction with race relations to African-American interviewers than to Caucasian interviewers. Caucasian respondents reported lower levels of

acceptance of African-Americans to Caucasian interviewers than to African-American interviewers. These results have been demonstrated repeatedly since then in a study by Schuman et al. (1985) It is important to note that more limited effects of race of interviewer and respondent have been observed on studies of other topics unrelated to race.

Another interviewer status examined in some detail has been gender. Earlier research has generally shown that the gender of the interviewer has no effect on responses to survey questions except when the content of the questions relates to sexual behavior or gender-related issues (Clark, 1952; Hyman et al., 1954). Research by Kane and Macaulay (1993) found that both male and female respondents express more egalitarian gender-related attitudes or greater criticism of existing gender inequalities to female interviewers. Furthermore, male respondents offer significantly different responses to male and female interviewers on questions dealing with gender inequality.

Age, as the third of the most visible ascribed status characteristics, has also been found to have only limited interviewer effects. School-age subjects have shown different responses to older verses younger interviewers for questions about peer influences. Younger interviewers obtained slightly more peer-oriented and less adult-oriented answers than older interviewers. With respect to age of respondents, research has shown that telephone surveys tend to underrepresent older respondents, but response distributions do not vary by telephone verses face-to-face interviews across age categories (Herzog et al., 1983). As with race and gender, age appears to have little effect on interview responses except when the topic being covered is directly related to the status itself.

Exchange Theory

The central assumption of exchange theory is that all interaction is based on ego's attempt to realize a 'social profit' by minimizing the cost of one's own actions and maximizing the benefits from alter's actions. The operating principle is that for interaction to continue, the norm of reciprocity must be followed such that the ratio of two parties' costs-to-benefits should be equal. If we view the interview as an exchange, it is relatively easy to define the benefits to the researcher: they are the data provided by the respondent that are his or her costs in time and effort in answering the questions. It is often more nebulous to define what the benefits to the respondent are, that is, the costs incurred by the interviewer that directly benefit the respondent. Of course, when respondents are being directly paid by the interviewer for their time, the benefits are clear and unambiguous. Market researchers, for example, sometimes establish panels of randomly selected respondents, who are paid for their time in a variety of repeated surveys. In short, they are 'professional respondents' for whom the exchange is a pure labor market transaction. Exchanges in kind may also be provided such as a lunch or dinner, a free gift, or a chance at a drawing. More often than not, however, the benefits are assumed to be some nebulous internal psychic reward that can include everything from the opportunity to vent one's opinions on a particular topic, that is, make use of a willing listener, to an increased sense of self-worth engendered by volunteering to help someone out, especially when the interviewer may have already appealed to one's 'specialness' by indicating that they have been 'selected' to participate. Altruistic appeals also redound to one's sense of self-worth, as when one is solicited as a respondent to provide data that may be useful in developing new policies and programs or evaluating existing ones even if one is not seen to be a direct beneficiary of them. Even the most abstract altruistic appeal – that by responding one is 'contributing to knowledge' – may at times work as a sufficient psychic reward.

What the exchange perspective highlights is that 'time spent' by the respondent is a very real but variable cost that may influence their willingness to be interviewed in the first place and their loquaciousness even if an interview is granted. The preciousness of 'time spent' doing an interview is differentially valued from one potential respondent to another (for example, the working mother vs the elderly retired nursing-home resident). Such calculations are highly likely to influence differential response rates in a selective or biased way. Not only are these calculations likely to vary from one set of statuses to another, but they will likely vary even for the same individual under different circumstances and in different situations such as time of day or day of week or season of the year, or at home, or at shopping, or work (Pol, 1992).

The cost of an interview is not simply one sided, for the interviewer's time is also a very tangible cost and one that must be taken into consideration often in a direct monetary way as when one is hiring interviewers or relying on a survey supplier. Such costs may have direct bearing on the nature and quality of the data gathered, for they can affect the length of the interview forcing real choices in research design as to sample frame and size, or number of topics explored and questions asked.

In short, from an exchange perspective, the interview is a cost–benefit transaction. The calculus of these varying costs to the interviewer/researcher must be weighed against the value of the data to be generated. In the design of surveys, for example, a distinction is often made between open-ended verses closed-ended questions, and the former generally prove to be more difficult and more expensive to code and analyze than latter. However, Geer (1991) found in an experiment that the open-ended comments are very effective in measuring the important concerns or 'salient' issues of respondents. In short, it appears to be the cost considerations as much as validity issues that have led to the dominance of forced-choice questions in survey research.

Costs and benefits of the interview also form a part of the calculus of the ethical considerations involving human subjects. Costs to the respondent slide over into a variety of 'risks' that may result from the disclosure of certain data and the loss of privacy. Anonymity or confidentiality may be required to forestall those costs. The idea behind 'informed' consent is that this calculus should be made by the subject/respondent based on a full disclosure of risks and benefits. Research in which there are substantial risks can only be justified by substantial benefits that outweigh these costs, and above all, it is up to the respondent to make this determination.

We should be aware that the utilities (value) of a respondent's cost/benefits may differ from those of the researcher and one is confronted with incommensurability, which may work to the advantage of the researcher. For example, an elderly

retired single respondent may have a surplus of free time, which is of low cost to give in answering a lengthy questionnaire, while to the highly trained interviewer this time is a valuable costly commodity in the research budget. Such incommensurability may at times work to the detriment of the interviewer when the inability to reach a common understanding of the relative value of information or time leads to an unwillingness to participate in what is considered to be a 'worthless' activity. (We note that this is one of the points of the symbolic interactionist perspective outlined below, which involves negotiating not only a common value but a common understanding of the meaning as well as the value of various social goods.)

Power Theory

The power or conflict perspective directly addresses the insight that much social interaction – and also the interview – involves differences in power among the parties. To be sure, power or conflict theory may be closely linked to either role theory (as when, for example, one talks about the differences in power that are present between the status of a male and a female in interaction) or exchange theory (as when the costs to participating in the interview are different for the interviewer and the respondent, or the benefits that one can provide to the other are different and one or the other party uses those differences in resources to extract what they want from the other). What the power or conflict perspective stresses is the reality that interviewer and respondent often have different degrees of power relative to one another and these may influence the nature and quality of the data generated in the interview.

Let us first address situations in which the interviewer has more power. We will use power in its broadest meaning to encompass the most subtle uses of prestige to the blatant uses of physical coercion. The latter is rare if ever present, but the former is quite ubiquitous. The imprimatur of an individual's title 'Doctor' or 'Professor,' or an institution's stature 'X University' or 'Y Agency' are often used to impress potential respondents as to the importance of the research and the desirability of their participating. In the actual conduct of the interview itself, power may be reflected in who makes the effort to initiate the contact or who travels to whom to conduct the interview. Being on one's home turf would seem to imply more power and control over the situation. A notable exception is the case in which elites may avoid being interviewed in certain situations (coming to their homes) in order to maintain a heightened degree of privacy. Researchers have sometimes strategically relied on the interviewer shifting out of the role of interviewer to becoming an observer and recording the presence or absence of such things as a piano, types of pictures and paintings hung on walls, and the use of curtains or drapes (Laumann and House, 1970). This is an example of combining methods in a multimethod strategy (Brewer and Hunter, 1990) to provide validity checks surrounding lifestyle and status and class variables.

At times, respondents may sense a threat from the interview situation that reflects a potential power differential between them and their interviewers. Potential threats may apply to divulging information concerning content areas that include socially undesirable and even illegal behaviors and could lead to not reporting or underreporting various forms of deviance and even criminal behavior ranging from drug use to official 'cheating' (Bradburn et al., 1979). Implicit threat could also lead to overreporting socially desirable behavior such as voting or charitable giving. There is some limited evidence that interviewer characteristics are related to threat. Respondents are willing to report socially undesirable behavior such as drug use to interviewers who are perceived to be more like themselves (Johnson et al., 2000).

The most widely used procedure to reduce threat is to eliminate the interviewer entirely or as far as possible from the data gathering process. In some cases, this means group administration of the interview in a public or quasi-pubic setting but where responses are private such as a school classroom setting. Even if the interviewer is present, it is possible that the threatening questions may be self-administered. Maximum privacy is obtained when the threatening questions are on a computer and the respondent reads questions from a screen. The respondent enters the answers directly into the computer and the interviewer is completely unaware of what answers are given (Tourangeau and Smith, 1996). It must be recognized that the use of self-administered methods reduces but does not eliminate respondent misreporting due to the power differentials in the interview situation and the potential threat of disclosure. It is precisely why the use and assurance of anonymity or confidentiality are not only ethical considerations but themselves may have a direct and positive impact on the validity of data generated through the interview.

Power is implicit in the very asymmetry of who asks questions and who answers them. The benefit is seen to be asymmetrical as the powerful ask questions of, glean information from, and acquire data about the less powerful. Much more rarely does information flow in the reverse direction – from the powerful to the powerless. Knowledge is power and its differential distribution is a means of obtaining and maintaining that power (Hunter, 1993).

Interviewing of elites is a situation in which the respondent often has more power than the interviewer. Such control may be reflected first in limiting the ability to gain access to begin with and continue through the interview situation with control over the content, format, recording, and even the use of interview data (Thomas, 1993). Although interviewers in their comportment should, of course, show respect to all respondents, an added degree of deference might be shown to those having more power or higher status than the interviewer. This deference could easily affect the likelihood of the interviewer's continuing to probe in finer and finer detail into the lives of the respondents, thereby limiting the quality and depth of the data.

The power differential enters as well into ethical considerations of the interview, and this is why interviews must be voluntary, since the countercase involving any form of coercion, no matter how mild, may be deemed unethical. For example, if a welfare recipient is being interviewed for research purposes, he/she might agree to participate in the interview if it is closely linked to the intake interview used to determine welfare eligibility, or a person in a public setting may agree to be interviewed out of a sense of peer pressure (e.g., students in a classroom setting). It is imperative that researchers be fully

cognizant of and sensitive to the power relations involved in the interview, as these may not only affect the quality of the data but reflect larger social processes of which the interview itself is a microcosm.

Symbolic Interaction

The interview situation is not one which is necessarily clearly defined and unambiguous, especially on the part of respondents. Therefore, one of the key activities of the good interviewer is to negotiate with the respondent in defining the appropriate behaviors and what can be expected in the interview situation. Drawing on the symbolic interactionist framework (Goffman, 1959), the interview may be considered to be a situation in need of mutual definition through the interaction of the interviewer and the respondent. At a minimal level is the idea that the interviewer is supposed to ask questions and the respondent is to give answers. But the fine nuances of this somewhat 'artificial' interaction are a negotiated reality in which the interviewer has the task of 'educating' the respondent into the appropriate behavior. For example, a too loquacious respondent might be interrupted in the course of an answer and asked to respond more simply – 'strongly agree, agree, neutral, disagree, or strongly disagree.'

The negotiated definition of the situation draws on the past experiences of both interviewer and respondent. The idea of interviewer training focuses on behaviors used to aid in an appropriate definition of the situation such as what to say to gain access, how to present self for gaining agreement to participate, how to develop and maintain rapport and how to terminate an interview, and of course, how to avoid biasing respondents (Billiet and Loosveldt, 1988). Some respondents may be familiar with the interview situation from having participated in them previously, while others may have been exposed to the situation vicariously through the media. Some may in fact be 'professional respondents,' that is, those paid to participate in ongoing panel studies in which they have been more thoroughly trained or educated into the respondent's role.

Expectations of the interviewer about the interview process have also been found to influence the nature of the respondents' participation. Some interviewer expectations are formed before the interviewer conducts any interviews, for example, expectations about how difficult or threatening certain questions may be to respondents, while other expectations may develop in the course of an interview as the interviewer begins to form a picture of the respondent through his/her prior responses, and yet other expectations may emerge as the interviewer completes multiple interviews and begins to form a patterned set of expectations for emerging 'types' of respondents. For example, interviewers who expected that questions about threatening behavior would be easy to ask received higher rates of responding than interviewers who thought the questions would be difficult to ask (Bradburn et al., 1979). It would appear that interviewer behavior in some way reflects expectations and that behavior calls forth different responses on the part of subjects.

Ambiguity in social interaction is a key problematic in the symbolic interactionist framework. Much interaction is seen to be specifically oriented to the reduction of ambiguity in an attempt to arrive at a mutually agreed upon definition of the situation. The issue of ambiguity is also significant in the interaction between interviewer and respondent. If a respondent should ask quizzically, what is meant by a question, often interviewers are simply instructed to repeat the question without further elaboration or clarification of the question so as no to differentially bias one respondent verses another. On the other hand, if a respondent gives an answer that is limited, partial, or ambiguous, the interviewer is often instructed to 'probe' to get greater clarification. In a classic laboratory experiment, Hyman et al. (1954) demonstrated that interviewers faced with an ambiguous response coded the answer on the basis of previous answers in the questionnaire. Respondents were asked a series of questions about whether the United States should actively intervene or should isolate itself from world affairs. When the response was ambiguous, those who had previously given unambiguously interventionist answers were coded as giving an interventionist answer, while those who had previously given isolationist answers were coded as giving an isolationist answer. In this experiment, interviewers were not allowed to probe the ambiguous answer for clarification.

The first phase of an interview involves negotiation in securing the willingness of the respondent to participate. By negotiating a formal 'commitment' from respondents in the form of a signed 'pledge' to answer 'fully' and 'truthfully' has been found to increase the degree of cooperation by respondents and the completeness of their responses (Cannell et al., 1981). A further mechanism for increasing cooperation is to flexibly tailor the appeal to participate to each individual respondent rather than using a standardized approach. Such individually tailored appeals generate higher levels of cooperation and also experienced interviewers are more likely to obtain such higher rates of cooperation (Groves and Couper, 1998).

A Multimethod Strategy

Interviews in their various forms and formats will continue to be a primary tool in the social scientist's tool kit for generating reliable and valid data. Direct comparisons of the interview with other tools for data generating, such as content analysis of media, or conversational analysis, the use of systematic observation of behavior, or the analysis of archives can only further the understanding of the strengths and limits of the interview in a multimethod strategy. Some but far too little research has been concerned with such comparisons. One example is Janet Lever's (1981) multimethod study of children's play. She found that interviews with kids produced more gender-stereotyped responses to the nature of boy's verses girl's play than observations of their behavior by the researcher or diaries kept by the kids themselves. Throughout the above discussion, the multimethod strategy has been mentioned at various points and briefly noted in passing. Bringing the multimethod strategy to the foreground whether narrowly focused on measurement or more broadly on the research process as a whole (Brewer and Hunter, 1990) can only lead to a more refined use of the interview in social science research. The shape

and function of the interview as a tool can more clearly be delineated as it is compared with these other tools in the same research project. The centrality and the ubiquity of the interview require much more systematic research, fully exploring the social, situational, and methodological dynamics of the interview process. Whether viewed from a postmodern perspective of a greater need for reflexivity within the social sciences or a positivist perspective of understanding the sources of bias and the need to reduce measurement error, much more research on the interview itself is needed. A few lines of inquiry and understanding have been developed as noted, but a great abyss of ignorance remains to be plumbed.

At various points throughout this discussion I refer to data being either 'gathered' or 'generated.' I fully recognize the implications of these two distinct concepts, as the former privileges an older classical positivism, while the latter speaks to a more agency-oriented social constructionist view of science. The distinction will itself become part of our nuance discussion of the interview.

Abstract

The contributions of Bruno de Finetti to probability and statistics are discussed. These include his celebrated exchangeability theorem, his theory of coherency, and his theory of finite additivity and adherent mass distributions. De Finetti was perhaps the primary exponent of the subjective theory of probability in the last century, and is to a large extent responsible for the resurgence of the Bayesian approach to statistics.

Bruno de Finetti was born in Innsbruck, Austria, of Italian parents on 13 June 1906, and died on 20 July 1985 in Rome. He enrolled in the Milan Polytechnic in 1923, and then after discovering that his interests lay more in science, switched to the Faculty of Mathematics of the University of Milan.

He first became interested in probability as a result of reading an article in a popular magazine concerning Mendel's laws of genetics, which stimulated him to write an article of his own on the subject. His article attracted the attention of Corrado Gini and eventually led to a position as head of the Mathematical Office of the Instituto Centrale di Statistica. Later he accepted a position as actuary in the Assicurazioni Generali insurance company in Trieste, where he was concerned with automation of all actuarial, statistical, and bookkeeping operations and calculations. He became a lecturer in mathematics, actuarial mathematics, and probability at the Universities of Trieste and Padova, and later full professor in Trieste and finally at the University of Rome, from which he retired in 1976.

In 1957 he spent a quarter at the University of Chicago at the invitation of Professor Leonard Jimmie Savage (1917–71). They became friends and each stimulated the other in the development of his ideas. Although there are differences in the presentations of subjective probability by de Finetti and Savage, their basic outlook was the same, and they stood in sharp contrast to other figures in the field, with the exception of Frank Ramsey (1903–30), whose important article *Truth and Probability* (1926) was very much in the same spirit. De Finetti and Savage were the major figures of the twentieth century in the area of subjective probability, and legitimate heirs of the two giants, Émile Borel (1871–1956) and Henri Poincaré (1854–1912), who also viewed probability theory as a serious subject with numerous important real-world applications, rather than as a mathematical exercise. Both de Finetti and Savage were infuriated by the trivializations of the subject as such an exercise, which dominated the field during most of their lifetimes.

Early in his career de Finetti realized that there was something seriously lacking in the way probability and statistics were being developed and taught. The famous remark 'Everybody speaks about Probability, but no one is able to explain clearly to others what meaning probability has according to his own conception,' by the mathematician Garrett Birkhoff (1940), was indicative of serious problems even with the definition of probability. De Finetti found many of the standard assertions confused and meaningless. In his University of Rome farewell address (1977), concerning the contrast between himself and Savage (a mathematician who had been trained in the standard non-Bayesian theory) he said: 'I, of course, was in quite the opposite situation: a layman or barbarian who had the impression that the others were talking nonsense but who virtually does not know where to begin as he cannot imagine the meaning that others are trying to give to the absurdities that it is imposing as dogma.'

De Finetti then attempted to formulate an appropriate meaning for a probability statement. His knowledge of philosophy and logic as well as mathematics, both pure and applied, enabled him to do so. The areas of his work that will be discussed here are his theory of exchangeability, theory of coherency, and theory of finitely additive probability. For him theory and practice were inseparable, and he emphasized the operational meaning of abstract theory, and particularly its role in making probabilistic predictions.

De Finetti rejected the concept of an objective meaning to probability and was convinced that probability evaluations are purely subjective. In his article *Probability and My Life* published in Gani (1982) he wrote: 'The only approach which, as I have always maintained and have confirmed by experience and comparison, leads to the removal of such ambiguities, is that of probability considered – always and exclusively – in its natural meaning of "degree of belief." This is precisely the notion held by every uncontaminated "man in the street." De Finetti then developed a theory of subjective probability, corresponding to its use as an expression of belief or opinion, and for which the primary feature is coherency.

The starting point for his theory is the collection of gambles that one takes on, whether knowingly or unknowingly. These can be either ordinary gambles or conditional gambles, which are called-off if the contingency being conditioned upon does not occur. The simplest type of gamble is one on an event E, in which one receives a monetary stake S if E occurs and nothing otherwise. If a person values such a gamble at the sure amount $p \times S$, then p is defined to be the probability of E for that person. In this evaluation one uses small stakes S so as to avoid utility complications, which distort probabilities evaluated in this way. One can then take linear combinations of such simple gambles to generate gambles in which there are a finite number of possible outcomes. Similarly, a called-off gamble on the event E given F is such that one receives a monetary stake S if both events occur, nothing if F occurs but not E, and the gamble is called off if F does not occur. The value of such a conditional

gamble for a person is called his or her conditional probability for E given F and is denoted by $P(E\backslash F)$.

In the work of de Finetti (1970, 1972, 1974–75) a primary aim is to avoid the possibility of a Dutch book, that is, to avoid sure loss on a finite collection of gambles. Thus suppose one has taken on a finite collection of gambles of any type whatsoever, including such things as investments, insurance, and so on. De Finetti proved that a necessary and sufficient condition for the avoidance of sure loss of a positive amount greater than some $\varepsilon > 0$ on a finite number of unconditional gambles, consists in consistency with the axioms of finitely additive probability theory. These axioms are the usual ones, apart from the fact that the condition of finite additivity replaces that of countable additivity in the third axiom. Let $P(E)$ denote the numerical probability for the event E. Then the axioms are:

1. $P(W) = 1$, where W is the sure event.
2. For any event E, $0 \leq P(E) \leq 1$.
3. The probability of a finite union of disjoint events is the sum of the probabilities.

Further, if conditional gambles are also included, then to avoid a Dutch book, conditional probabilities must be evaluated in accord with the usual definition:

$$P\{A|B\} = P\{A \textit{ and } B\}/P\{B\},$$

provided that $P\{B\} > 0$. See Hill (1998) for further discussion.

In the subjectivistic conception a probability is essentially a price that one will pay for a certain gamble, with the understanding that this price can and will differ from one person to another, even apart from utility considerations. This conception is very close to that of the common person who speaks of probabilities for various real-world events based upon his or her own experience and judgment. In this case there is no need to confine attention to trials such as arise in games of chance. On the other hand, it is extremely interesting to see what the subjectivist interpretation of such trials might be. By considering this question, de Finetti developed his celebrated exchangeability theorem.

The problem that de Finetti posed and largely solved was that of justifying from a subjective point of view the importance of statistical frequencies in the evaluation of probabilities. Suppose that we have a sequence of events, E_i, for $i = 1, \ldots, N$, each of which may or may not occur, for example where E_i is the result of the ith flip of a coin. For convenience, we can assign the value 1 to heads and 0 to tails. It is natural sometimes to view the order of the flips as irrelevant, so that any permutation of the same sequence of outcomes is given the same probability. This leads to the notion of exchangeability, which is a symmetry condition, specifying that joint distributions of the observable random quantities are invariant under permutations. De Finetti proved a representation theorem which implies that if one regards a sufficiently long sequence of successes and failures as exchangeable, then it necessarily follows that one's opinions can be represented, approximately, by a mixture of Bernoulli sequences, that is, of sequences for which there is a 'true' (but typically unknown) probability P of success, and such that conditional upon $P = p$, the observations are independent with probability p of success on each toss. The proportion of successes, as the number of trials goes to ∞, converges almost surely to P, and the initial or *a priori* distribution for P is also called the de Finetti measure for the process.

This representation in terms of Bernoulli sequences is exact for infinite sequences, and a slight modification holds also for finite sequences, the difference amounting to that between sampling with and without replacement from an urn. It also follows mathematically that provided a sufficiently long sequence has been observed, to a good approximation one will be led to base opinions about a future trial on the past empirical frequency with which the event has occurred, and this constitutes de Finetti's justification for induction. In his work de Finetti emphasized prediction of observable quantities, rather than what is usually called inference about parameters. In other words, he was primarily interested in the posterior distribution of future observable random variables, rather than in the posterior distribution for the parameter P. This point of view has become known as predictivism in modern Bayesian statistics.

The exchangeability theorem of de Finetti allows one to analyze the relationship between subjective probabilities and the frequency theory of probability that developed from the work of Jakob Bernoulli. The fundamental stochastic process is known as a Bernoulli sequence. Such a sequence is by assumption such that on each trial there is a fixed objective probability p for success (1) and $1 - p$ for failure (0), whose value may or may not be known, with the trials independent in the probabilistic sense. It is then a mathematical fact, known as the law of large numbers, that as the number of trials grows large the proportion of successes will stabilize at the 'true' probability p in the sense that the proportion of successes will converge almost surely to p; that is, the sequence converges except for a collection of outcomes that has probability 0.

Critics of this theory, such as de Finetti, argue that there are no real-world applications in which either p or the limiting proportion of successes is known to exist. The empirical support for the objectivist theory is merely that there are certain processes, such as coin flipping, dice throwing, card playing, draws from an urn with replacement, and so on, for which in finite sequences of trials the empirical proportions of successes appear to be in conformity with what the objectivist theory suggests. For example, if there are two similar balls in an urn, one red and one white, and if draws are made with replacement after substantial shaking of the urn, then experience suggests that the proportion of red balls in n draws, when n is sufficiently large, is around .5. Of course it is impossible to perform an infinite number of trials, so the limiting proportion, if it exists at all, can never be known. But in finitely many trials not only does the proportion of red balls drawn often seem to settle down to something like .5, but in addition, if say the n trials are repeated I times, then the proportion of these I trials in which there are exactly j red balls in n trials appears also to settle down to $\binom{n}{j}(1/2^n)$, more or less as the theory suggests. One must, however, exclude situations where such settling down does not appear to happen, and these are usually interpreted as meaning that the shaking was not adequate, or the cards not sufficiently well shuffled, and so on. Nonetheless, it

appears that when sufficient care is taken, then the proportions appear to be roughly in accord with the objectivistic theory.

Does this imply that there exists a true $p = \frac{1}{2}$ which is the objective probability, for example, that the ball drawn is red, and hence also that the proportion of red balls drawn must converge almost surely to .5? No one knows to this day. However, de Finetti's exchangeability theorem provides an alternative way to describe our experiences with such random events. A probability as before is merely a price that one would pay for a certain gamble. Under the assumption of an equal number of red and white balls, and that the urn is well shaken, symmetry suggests a price of .5 for the gamble in which you receive a dollar if a red ball is drawn, nothing otherwise. Similarly, if you were to be offered a gamble in which you would receive the dollar if the first two draws were red, then again symmetry together with the assumption that the urn is well shaken, suggest that a fair price would be .25. Continuing in this way we see that your prices are in accord with the usual probability evaluations for such an urn.

It is then a logical consequence of the exchangeability theorem of de Finetti, that you must evaluate your probability that the sample proportion of red balls converges to .5 as unity. Note that this requires no circular definitions or mysterious conventions. There are, however, two important caveats. First, it is necessary that utility considerations be ignored, which necessitates that the prizes are not too large, and for this reason the stake S was taken to be one dollar. Alternatively, utility can be dealt with after the fashion of Ramsey or Savage. Second, the cases where people take this evaluation most seriously are those in which there have already been many draws in the past, indicating no cheating or violation of the apparent symmetry, so that in effect your probabilities are posterior probabilities based upon Bayes' theorem. In other words: just as dice may be loaded so can other games be fixed, and a prudent bettor would not make the above evaluations merely from apparent physical and time symmetry alone, but rather in addition from experience that the game is not rigged and that the perception of symmetry is not mistaken. At any rate, one sees that it is not necessary to introduce the concept of an objective probability, but merely the experience that suggests an evaluation of .5.

The case of a Bernoulli sequence, whether interpreted according to the objectivist or subjectivist theory, is of course a very special example of an exchangeable sequence of random variables. For a Bernoulli sequence with $p = .5$, that is, a degenerate *a priori* distribution for P concentrated at the value .5, the primary difference between the two theories is that the objectivist theory objectifies the .5 which in the subjectivist theory is merely the opinion of the bettor, and similarly the .25 for drawing two red balls, and so on. In circumstances where prudent bettors have learned from experience to bet in accord with symmetry, the objectivist school states that the .5 and the .25 and so on are the objective or true probabilities, not merely the values that the bettor chooses. Thus the objectivist theory implies that the proportion of successes necessarily converges to .5, while the subjective theory implies that the bettor must believe, with probability 1, that such convergence takes place.

It should be noted that countable additivity, that is, the modification of the third axiom to include also denumerable unions of disjoint events (which corresponds to a denumerable number of gambles) has never been demonstrated within the rigorous approaches to probability theory and, as argued by de Finetti, is merely a particular continuity condition that one may or may not wish to adopt in a particular context, just as with the use of continuous functions in physics. The relaxation of the condition of countable additivity to finite additivity allows one greater freedom in the representation of degrees of belief. For example, the use of adherent mass distributions (which were introduced by de Finetti and are closely related to Dirac functions) allows one to obtain solutions for Bayesian non-parametric inference and prediction. See Hill (1993).

The work of de Finetti played a major role in the resurrection of the classical Bayesian approach to probability, statistics, and decision theory, as founded by Bayes and Laplace and developed by Gauss, Poincaré, and Borel. His work continued the theory of induction of the British empiricists such as David Hume, and provided mathematically sound foundations for the modern-day subjective Bayesian approach.

Abstract

Death is an inevitable part of life and how an individual approaches the death and dying process is a phenomenon that continues to be examined. Ultimately, how an individual reacts to death and dying is dependent on a variety of factors, including death attitudes, developmental statuses, and cultural considerations.

Death is an inevitable part of life and how an individual approaches the death and dying process is a phenomenon that continues to be examined. Ultimately, how an individual reacts to death and dying is dependent on a variety of factors, including death attitudes, developmental statuses, and cultural considerations. Using Erikson's (1963) psychosocial stages as a framework can help understand how these factors affect individuals coping with loss or their own impending death throughout the various stages of life.

Overview of Death and Dying Perspectives

There is an extensive history associated with the desire to understand death and dying. Research on attitudes around death began in the 1950s when Feifel (1959) laid the foundation for investigating death attitudes and anxiety and establishing the field now known as thanatology, the study of death and dying. Glasser and Strauss (1965) were also early voices in death research, discussing the influence of awareness with dying individuals. Research has continued and expanded, examining various age ranges of individuals and cultures, providing a more comprehensive understanding of death attitudes. Scales measuring death anxiety (Schell and Seefeldt, 1991; Thorson and Powell, 1992), fear of death (Lester, 1990), grief reactions (Hogan et al., 2001), and many others have been developed to provide more scientific understandings of grief and death. Theories centered on coping with grief, such as the five stages of grief and the dual process model of coping with bereavement, have been created to help understand grief trajectories and provide practitioners with resources to support bereaved or dying individuals (Kubler-Ross, 1969; Stroebe and Schut, 1999).

Important consideration in understanding death attitudes and development are psychosocial stages. Psychologist Erik Erikson (1968) categorized the various stages of life according to psychosocial development (*see* Theories of Human Development). At the center of this psychosocial stage theory are ego identity and competences. Ego identity is shaped by social interactions that help develop attitudes, beliefs, and values. Competences refer to individual tasks throughout the stages of life that impact ego identity development. When approaching death, death attitudes and personal wellness are explicitly linked to specific psychosocial stages throughout life.

Death Attitudes

Death attitudes are often defined as the fear and anxiety related to end of life and dying (Neimeyer, 1994; Neimeyer and Hogan, 2001). They are influenced by a number of factors in an individual's life, including age, gender, race/ethnicity, cultural norms, physical and psychological health, religious/spiritual beliefs, previous experience with death, and life satisfaction (*see* Death and Dying, Sociology of). These factors, combined with an individual's age and developmental stage from childhood to adulthood, significantly impact their attitudes and views toward death and dying.

Childhood and Death

Early research on childhood death attitudes indicated three distinct developmental stages: nonfunctionality, irreversibility, and universality (Nagy, 1948). The first stage of nonfunctionality refers to the understanding that specific living functions, such as breathing, end at death. The second stage of irreversibility focuses on the understanding that a human body cannot physically return from death after dying. The third and final stage of universality refers to the understanding that living things will eventually die.

Children specifically under the age of 5 may perceive death as reversible, or the result of magical or medical mediation (Speece and Brent, 1992). Children aged 5–9 often personify death. They also view it as escapable instead of inevitable. Most children aged 9 and above recognize that death is universal, irreversible, and that human functioning ceases; however, research also shows children develop mature understandings of death as early as age 6 (Hunter and Smith, 2008; Mahon et al., 1999; Nagy, 1948). Overall, female children express more resistance to and have negative emotions about death, male children are more likely to accept and confront death (Yang and Chen, 2009) (*see* Infancy and Childhood: Emotional Development).

The attitudes children have toward death vary among gender and are largely influenced by their cognitive development, religions, socialization, and prior experience with death and dying (Mahon et al., 1999; Morgan and Laungani, 2002; Silverman, 2000; Yang and Chen, 2009). An important consideration in understanding death attitudes in children is development and psychosocial stages. Erikson (1963, 1968) characterizes each of the four stages in childhood with

the developmental tasks of trust, autonomy, initiative, and industry. Confrontation with death or dying can significantly impact the developmental fulfillment of these tasks. For example, the developmental task of infants involves the cultivation of trust. This allows children to develop a sense of hope and the ability to rely on others to fulfill their needs. Terminally ill infants with changing care providers and hospital settings can cause disruption to fulfilling this developmental task (Doka, 1996). The psychosocial stage shifts to independence and self-control in later childhood (Erikson, 1963). This can be stressful for young terminal toddlers suffering physical limitations due to terminal illness (Doka, 1996).

During early childhood, children begin balancing their personal desires with their moral responsibility. Children in later childhood are concerned with productivity and mastering skills (Erikson, 1963). These tasks become troublesome for terminal children who are limited by physical barriers, parental apprehension, and safety concerns, thus affecting self-esteem and achieving developmental competencies (Doka, 1996).

Adolescents and Death

Adolescent attitudes toward death are also explicitly linked to developmental issues (Noppe and Noppe, 1996). The concepts of death for younger teens involve parental separation, and concepts for mid-adolescences focus on death impact. Legacy is at the forefront for college-age youth and personal identity is an important development in this psychosocial stage (Erikson, 1963). Struggles with identity development can impede a logical understanding of death and increase death anxiety (Noppe and Noppe, 2004). The highest levels of death anxiety among teens occur among those who possess 'less stable ego pictures' at the peak of identity formation (Alexander and Alderstein, 1958: p. 175).

Identity formation is significantly impacted for terminally ill adolescences (*see* Identity in Childhood and Adolescence). Physical changes associated with puberty may be delayed or replaced by side effects of medical treatment, including hair loss, acne, weight fluctuations, or disfigurements (Freyer, 2004). The need for physical and emotional support and dependence can initiate struggles for independence and affect psychosocial development (Nannis et al., 1978; Freyer, 2004). Isolation can occur affecting identity formation and peer socialization (Freyer, 2004).

Adulthood and Death

Similar to earlier life stages, adulthood attitudes toward death are also influenced by gender, ethnicity, physical and psychological health, religious beliefs, environmental factors, generational differences, experience with death and aging, life satisfaction, and impact death attitudes (DePaola et al., 2003; Fortner and Neimeyer, 1999; Walker and Maiden, 1987). Death anxiety typically decreases as age increases; however, death anxiety peaks for women in the mid-20s age range and then again in the early 50s (Russac et al., 2007). Older women also tend to report more death anxiety than men (Azaiza et al., 2010; Besser and Priel, 2007; Cicirelli, 2001; DePaola et al., 2003; Suhail and Akram, 2002).

Death attitudes also vary among cultures and environment (*see* Health and Illness: Mental Representations in Different Cultures). Older Caucasian adults report fears pertaining to the dying process, while African-Americans experience fears of what proceeds death, such as fear of the unknown, consciousness when dead, and the status of the body after death (DePaola et al., 2003). Older adults with less religiosity exhibit greater anxiety about various dimensions of death (Cicirelli, 2002; Suhail and Akram, 2002; Wu et al., 2002). Older adults living in institutions show more fear of death when compared to older adults living independently (Azaiza et al., 2010; Fortner and Neimeyer, 1999). Older adults with physical and psychological ailments or concerns also experience greater death anxiety (Moreno and Moore, 2008; Wu et al., 2002). Finally, hospice patients who have more experience with death experience lower levels of death anxiety and avoidance (Bluck et al., 2008).

When facing death, the responsibilities and competencies that young adults practice and the intimacy they desire are strained (Cook and Oltjenbruns, 1998; Erikson, 1963). Young adults have established their identity and commitments to friendships, marriage, parenthood, and careers. When impending death or a terminal illness intrudes upon this stage of life, young adults can be resistant of their prognoses (Pattison, 1977). Terminal illness can cause young adults to experience fear about the dying process and alienate their partners, threatening important relationships.

While relationships remain important in the later stage of adulthood, the psychosocial stage of older adults centers on achievements and generativity (Butler and Lewis, 1982; Erikson, 1963; Pattison, 1977). Impending death triggers individuals to reflect on their life accomplishments (Cook and Oltjenbruns, 1998). Generativity is a term that Erikson (1968) refers to when an individual becomes focused on legacy, such as parenting and future generations.

Finally, the concerns among the elderly when facing death center on a life review, which are closely linked to ego identity (Butler, 1963; Erikson, 1963). Life reviews provide the dying elderly with feelings of wisdom, acceptance, fulfillment, and contentment, thus maintaining their ego before death. Unfortunately life reviews that are not validating can generate feelings of hopelessness, disappointment, and an unfulfilled life (Erikson, 1982).

Cultural Considerations

While Erikson's (1963) psychosocial stages provide a solid framework for using attitudes around death, specific cultural factors should also be considered (Parkes et al., 1997). For example, Chinese culture has significantly different views on death and dying, stemming from their beliefs rooted in Buddhism, Confucianism, Taoism, and traditional Chinese medicine. Even speaking of issues around death and dying is believed to bring back luck, thus creating a culture where talking about death is taboo (Hsu et al., 2009).

In the Islam culture, vast differences exist between men and women which affect grief practices. Kobeisy (2004) notes that "the primary role of women has become one of wife and mother within the extended family in a patriarchal society with little concern or awareness of life outside her home" (p. 46). Focusing

specifically on grief and loss, expectations for men are to control their emotions, maintain composure, and express grief quietly while women are allowed to express more emotion, but are not allowed to attend funerals (Rubin and Yasien-Esmael, 2004).

Coping with Death and Dying

One of the most widely known theories surrounding death and dying is the stages of grief model presented by Kubler-Ross (1969). Although this model has not been proven through empirical research, it has been used by bereaved individuals and clinicians to help understand grief and aid with coping. The fallacy with the stages of grief is not only due to the lack of scientific evidence to prove it, but its impractical nature as well. Human beings grieve in individual ways that cannot be confined and defined by five stages. Furthermore, circumstances surrounding death events, such as cause of death, relationship to the deceased, support systems, and cultural considerations, also affect the trajectory of bereavement and preparation for death and are not addressed within the stages (Goldsmith et al., 2008; Wen et al., 2011). Kubler-Ross conducted her research only with patients who were dying, not those who were grieving a loss, therefore the major contributions of her work were opening the conversation about grief and loss and providing a more in depth understanding of the dying process.

Another established model is the dual process of coping with bereavement model (Stroebe and Schut, 1999). Instead of taking a stage approach to the coping process, the dual process model divides bereavement into loss and restoration. Loss includes engaging in grief work including feelings of both acceptance and denial. Restoration involves the simultaneous process of the bereaved learning how to live a new way of life without the deceased, thus restoring their lives. While this model provides a new perspective on coping with loss, the limitation is that it is restricted to individuals coping with a loss of another individual and does not include the dying self.

A more recently developed model is the Holistic Impact of Bereavement (Balk, 2011). This framework was developed to illustrate the multidimensional effects of grief on grieving individuals. Through several years of research with college-aged students, Balk found that grief affects the bereaved physically, cognitively, behaviorally, interpersonally, emotionally, and spiritually and can manifest in various ways. Although they do not refer to the Holistic Impact of Bereavement specifically in their research, numerous research studies have similar findings (Neimeyer et al., 2008; Servaty-Seib and Hamilton, 2006; Walker et al., 2012).

Additional bereavement theories and models, such as the Grief to Personal Growth Model (Hogan and Schmidt, 2002), ATTEND (Attunement (A), Trust (T), Touch (T), Egalitarianism (E), Nuance (N), and Death (D)) (Cacciatore and Flint, 2012), and Meaning Reconstruction Theory (Neimeyer and Anderson, 2002) have also been developed to help dying or bereaved individuals. Each of these approaches provides an important and unique understanding of the coping process. Similar to understanding death attitudes, it is also important to understand developmental and cultural considerations when examining such models.

Conclusions

Death and dying are inevitable experiences in life. They are also complex processes. How a person perceives these phenomena is directly impacted by their stage of life and level of development – and development is significantly impacted by dying as well. Additional factors, such as gender, culture, social support, and others also inform attitudes about death and dying. Therefore combining all these characteristics makes the death and dying process an individualized one that elicits individualized perspectives and experiences.

Further Research

The knowledge gathered by thanatologists, psychologists, medical researchers, and other interested parties has provided a breadth of information on the death, dying, and grieving processes with more yet to be learned. As the world becomes more technologically advanced and ever-changing, research must follow the change and growth. Death and dying research is no exception.

As the number of people turning to the Internet for health-related information and support increases, more attention has been given to how dying and bereaved individuals use the Internet for support (Sofka et al., 2012; Walter et al., 2012). Recent studies have examined the use of support groups to provide grief support, Web memorialization of deceased loved ones; and how social networking impacts the grief process (Dominick et al., 2009; Hieftje, 2012; Roberts, 2004; Tolstikova and Chartier, 2009; Varga and Paulus, 2013). Continued attention must be given to these expanding uses of support to further understand the human response to death and dying.

As the world experiences more contemporary disasters, it is important to understand how these events affect psychology associated with death and dying. New studies have shown that these contemporary disasters are affecting children and instilling new fear (Burnham, 2009). Continued research on other individuals and those in other areas of the world experiencing disaster should be closely examined.

Finally, another area in need of continued research is physician assisted suicide (*see* Suicide: Ethical Aspects). As individuals, particularly in the United States, seek to make their own end-of-life decisions, it is important to understand the outcomes and ramifications of these procedures on individuals, families, and communities (Cerminara and Perez, 2000). As medical technology advances, individuals with decreased quality of life may increasingly turn to this form of accelerated death (Sears and Stanton, 2001). This desired control over the end-of-life process will certainly provide new perspectives on the psychology of death and dying.

Abstract

Social processes that influence contemporary dying and grieving include secularization, medicalization, professionalization, and sequestration. Sociological research on awareness and trajectories of dying has influenced health care systems toward more open communication styles at the end of life, intended in part to delay the onset of social death to as near as possible to physical death. The recent shift from funerals displaying social status to displaying the deceased's individuality may be understood in terms of postmaterialism. Sociological studies of bereavement are relatively underdeveloped, though the concept of disenfranchised grief has been influential. Recent research links the politics of memorialization to sociological theorizing of collective memory, and examines how the Internet socially relocates the dying, the grieving, and the dead.

Whereas demography measures and seeks causal explanations for variations in mortality rates, the sociology of death and dying is concerned with the role of mortality in social life. Many social thinkers believe that death poses the fundamental threat to the integrity and continuity of society. Social structures must provide a 'symbolic canopy' that guards against the terrors of extinction by providing meaning to human activity (Berger, 1969). Societies respond to this threat in a wide variety of ways ranging from the collectivist, death-accepting, rebirth orientation of much of the East, to the personal, death-defying, hedonism of much of the West. The sociology of death and dying, therefore, provides a unique perspective to investigate the core values of a culture. The discipline has been greatly influenced in content as well as methodology by psychiatry, anthropology, and social history. A main focus has been on changes in experience, attitudes, and roles of the dying, the bereaved, and their professional helpers.

A Broken Connection?

Does society comprise only the living, or does it also include the dead? It has often been asserted that traditional societies, especially those that venerate ancestors, comprise both the living and the dead, while modern Western societies have cut themselves off from the dead. This, however, is debatable. Almost every new communication technology, from writing to the Internet, has expanded the possibilities not only for the living to communicate with the living, but also about or even with the dead. *How* the dead are present in society, and what social institutions they legitimate, is subject to change. In many tribal societies, oral storytelling about the ancestors serves to construct and legitimate membership in an extended family. In the modern world, printing, mass literacy, and universal education (including the teaching of history) have enabled the exemplary life and often heroic death of national heroes to be used to construct national identity (Marvin and Ingle, 1999). Through photography and sound recording, deceased celebrities can continue as economic actors, often grossing more after than before death (Kearl, 2010). The Internet provides intriguing new possibilities for the living to interact with the dead (Walter et al., 2011–2012).

If the dead, or certain of the dead, continue among us as political or economic actors, what about the more everyday dead with whom we were intimate in life? Despite many bereaved people experiencing various kinds of continuing bond with the dead (Klass et al., 1996), Secularism and Protestantism have no ready language with which to describe this, acknowledging that the dead may continue on earth in memory or possibly in heaven as a soul, but cut off from the living and certainly not social agents. Where and what the dead are envisaged to be depends on culture and religion: "In the West, post-death conceptions typically involve the integrity and continuity of one's personal self. In the East, the ultimate goal is often an undifferentiated and impersonal oneness with the universe" (Kearl, 1989: p. 27). Literal and symbolic responses to questions about the dead, therefore, provide key insights into culture.

Concerning personal experience of dying or grief, traditional societies are characterized by widely shared and explicit norms of social behavior in general, and of mortuary ritual in particular. People knew how to behave when faced with death and dying. In many modern societies, individuals no longer have such clear social rules to guide their behavior (Gorer, 1965). They often feel confused or uneasy, and a number of demographic and social trends have been posited as underlying this.

Impact of Recent Trends

There have been significant changes in how death, terminal illness, and mourning are experienced and managed in the West (Blauner, 1966). Until the late nineteenth century, death was common at any age and especially in infancy, childhood, and childbirth; a relatively short illness caused by infectious disease was the most likely precursor to death. Today, death is most commonly caused by the degenerative diseases of old age, and dying can take months or years. Most of those near the end of life have long completed their main roles in work and family, and are hidden away in hospitals and elder care facilities; thus death has become separated from life, and young people do not learn about it from direct observation. In addition to these changing demographics, a number of social

processes such as secularization, medicalization, and sequestration have been implicated in the modern management of death.

Secularization

From a religious perspective, dying was the 'defining moment' in a person's life (Seale, 1998). Typically, a religious authority would assist at this feared rite of passage to 'the next world.' With the decline of religious belief in general, and of fear of damnation in particular, death lost much of its sacred or theological importance. Instead death became a time of separation from loved ones at the ending of a human life, while dying increasingly became a private act. The shift from religious to secular is illustrated by changes in the image of a 'good death.' Many modern secularists and even religious people now wish for an 'unconscious death,' a painless sudden demise during sleep, which in the Age of Belief was considered an 'accursed death' because it left no opportunity for the dying person to prepare to meet his or her maker (Ariès, 1974). Gorer (1965), in a widely cited monograph, argued that death had replaced sex as the modern form of pornography, an embarrassing taboo topic. Becker (1973) claimed that although fear of death was universal, modern society was characterized by a pathological 'denial of death.'

Professionalization

As the majority of people began to die in hospitals, death and dying gradually came under medical control. Some criticized the resulting bureaucratic organization of care as constraining and shaping the behavior of doctors, nurses, patients, and families in ways they often do not understand (Kaufman, 2005). With medicine oriented toward cure, incurable patients risked physical and emotional isolation, characterized by Elias (1985) as "the loneliness of the dying." In response to this, the hospice and palliative care movement has attempted to humanize dying, acknowledging its emotional, social, and spiritual as well as physical aspects, though from a Foucauldian sociology of power perspective, this entails medical surveillance being extended beyond just the patient's body to their entire being (Clark, 1999).

Outside of palliative care, the dramatic rise of life-support technology created situations in which a person was neither fully alive nor completely dead. As a result, medicalized death lost its status as a defining moment, but became instead an arbitrary time when the machines were finally turned off. "Death in the hospital is no longer the occasion of a ritual ceremony, over which the dying person presides amidst his assembled relatives and friends. Death is a technical phenomenon obtained by the cessation of care" (Ariès, 1974: p. 88). This situation also created a need for new definitions of death, the most widely accepted being that of brain death or, more controversially, the demise of the cerebral cortex, associated with the irreversible loss of personhood. Brain death, which opened up the possibility for the transplantation of organs, was widely accepted in the West but remains highly controversial in Japan (Lock, 2002).

The standard narrative in the history and sociology of dying, reflected in the paragraphs above, posits a historical shift from religious dying within a known community to medicalized dying, whether isolated in a bureaucratic hospital or holistically cared for in a hospice. Doctors thus tend to get portrayed as the bad guys – not actually a view held by most modern citizens, who would far rather live to a pain-controlled old age, even if ending in hospitalized social isolation or a technologically induced social death, than to die young and in agony from cholera. Allan Kellehear (2007), however, argues that in a really long-term historical perspective, those who first took dying away from communities were not medical but religious professionals; this occurred with the rise of the world religions in the ancient world. In this view, the key issue is not medicalization but professionalization, and indeed contemporary holistic care of the dying does add a whole new raft of professional groups to the 'multidisciplinary team's' clinical gaze. This has recently led to some radical initiatives attempting to return responsibility for dying to communities, even within complex urban settings (Conway, 2011).

Sequestration

Sociological accounts of death in the modern era often draw on a narrative of a supposed decline of community. The dying and the bereaved become isolated, and grief in particular gets defined as an inner psychological process rather than a shared social experience (Walter, 1999). Whatever merits the Freudian concept of denial may have within a psychological perspective (Becker, 1973), some sociologists have argued that other concepts are needed to make sense of the social position of those personally confronting death (Kellehear, 1984). Chief among these is sequestration, which points to the isolating not only of death but also of other troubling aspects of the human condition such as madness, from everyday life (Mellor and Shilling, 1993). With the dying hidden away in hospital, and the loss of mourning attire rendering the grieving invisible, death disappears from public discourse, yet remains an intense personal experience for those who themselves are dying or grieving. Others, however, have argued that the public/private relationship may be the other way around: with many not having to face significant bereavement until their 30s, yet with images of death ever present in the mass media, death is perhaps more present in public than in private. Either way, relationships between public/private and individual/community have been of considerable interest to sociologists of death.

Sociology of Dying

Sociological studies of dying have focused on care of dying people, rather than the experience of dying. A landmark study was done by Glaser and Strauss (1965, 1968) who developed two frameworks for analyzing the interaction between the dying person and medical staff: awareness contexts and dying trajectories.

Awareness of Dying

'Awareness contexts' referred to the degree of shared knowledge between patient and doctor concerning the fatal prognosis,

which ranged from 'closed,' where only the doctor knew, through intermediate stages – 'suspicion,' 'mutual pretense' – to 'open' when both parties could freely discuss the terminal illness. At the time of the original study, closed awareness was the norm, and arguably the study proved to be one of the most effective ethnographies in any field of sociology in terms of promoting change in policy in practice. By describing hospitalized dying, it caused readers to ask if they wanted to die like that, and many replied in the negative; doctors in individualistic Western societies are now much more open both about diagnoses of cancer, and of its subsequent end stages, though closed awareness remains common in more collectivist and/or family-oriented countries like Japan or Italy.

Dying Trajectories

Dying trajectories are "perceived courses of dying rather than the actual courses" (Glaser and Strauss, 1968: p. 6). The trajectories were based on the "time for dying" (Glaser and Strauss, 1968) as expressed in a pair of dichotomies: expected/unexpected, sudden/lingering. This produced four basic trajectories: sudden unexpected, most commonly seen in the emergency room; sudden expected, common in intensive care units; lingering unexpected as in the uncertain course of AIDS patients and many frail old people; lingering expected, as in the final stages of cancer. Each hospital ward was thus geared to a specific dying trajectory and used specific strategies to maintain its routine or 'sentimental order.' Medical personnel and family members experienced most distress when an actual trajectory deviated from its predicted course.

Social Death

Humans are born as primarily physical beings who then steadily acquire an existence that is increasingly shaped by culture. In many forms of dying, there is a reversal of this process as the dying person 'falls' from culture back into nature (Seale, 1998). "Much of the time I feel I'm just a body to be fed, watered and toileted," a friend, once vibrant but now in frail old age, told me a few weeks before she died, at home. Kept alive in hospital on life-support, the feeding, watering and toileting may be done automatically and impersonally through tubes and pumps.

A similar sociological concept is that of social death (Mulkay and Ernst, 1991). This concept shows that the end of a person's social life may not coincide with the end of their physical life. The person in a coma, or with advanced dementia, may no longer be related to as a person with agency; thus relatives may feel that the person has 'already died.' In non-Western cultures in which relationships are more important than individual autonomy, experiences of dependency and care may differ.

Communication and Control

Many modern Western individuals who value personal autonomy fear ceasing to be a social actor, becoming just a body to be done to by others. To mitigate this fear, contemporary health care agendas promote choice and control toward the end of life; the aim is to enable people to live socially for as long, or almost as long, as they live physically – to continue for as long as possible as cultural beings and social agents, not just physical bodies. Palliative care and euthanasia, though ideologically opposed in some countries, offer different routes to the same goal of reducing the time gap between social and physical death. Palliative care strives to extend social life as long as possible; euthanasia offers the choice to bring forward physical death to before social death sets in. Both value patient choice and control.

Contemporary health care discourse now "redirects incoherence, anxiety, breakdown, diffuse suffering, and any other expression of affect that lacks rationality" into control, choice, and the good death (Kaufman, 2005: p. 17). 'Choice' and 'control' are neat, abstract concepts that assume individual autonomy. But according to Kaufman's American hospital study, choice and control are illusions. As in both consumerism and neoliberal governmentality, patients and families are required to choose, but only at certain times, and only certain choices are available. Patients and families do not understand the system that undergirds this, and so are not prepared. Nor is prognosis an exact art, especially when cancer or AIDS are not involved. Meanwhile, Western medical ethics continue to promote patient autonomy as a key principle in end of life care.

Funerals

In contrast to considerable research into care of the dying, much less attention has been given to the sociology of the dead. Sociological studies of funerals have mainly looked at the funeral industry, whether from the point of view of professionalization (Pine, 1975) or economic sociology (Suzuki, 2001). What is strikingly lacking are sociological theories of the funeral rite itself; the few empirical studies that have been done tend to be through the eyes of professionals such as funeral directors and clergy, very occasionally the bereaved family, and almost never the whole congregation of mourners. Classic anthropological theories of rites of passage have proved difficult to apply to modern Western societies.

It is clear, however, that funeral rites in many Western countries are changing – from looking forward to heaven to looking backward to celebrate the deceased's earthly life; from displaying social status to displaying the deceased's individuality. Such shifts may be understood not only in terms of secularization but also in terms of postmaterialism. According to Ronald Inglehart, postindustrial affluence and security produce a new – postmaterial – cultural formation (Inglehart and Welzel, 2005). As people come to take physical and economic survival for granted, so their values shift toward self-expression, subjective well-being, and quality of life. These are precisely the values promoted by palliative and bereavement care, but the implications are most dramatic for funerals. In many rural societies, funerals were a time for the community to come together. With industrialization, people moved (often across continents) to new industrial towns and became concerned with class and status, that is, with finding their place in the new class-based urban society. Thus funerals became a way of displaying class and status position, as in the nineteenth century British funeral, or the mid-twentieth

century American funeral lampooned by Jessica Mitford (1963); only in death did many mid-century Americans get to ride in a Cadillac! By contrast, today's postmaterialists – secure within a stable middle class position – no longer need to display status, and increasingly use the funeral to display not status, but lifestyle – the unique lifestyle of the deceased.

Postmaterialism has implications also for the funeral's material trappings. Confidently upwardly mobile American baby boomers reject the mid-twentieth century baroque American funeral and instead display their good (postmaterial) taste by abandoning status display and opting for a simpler cremation. In the UK, where a minimalist cremation rite has been the norm for 50 years, postmaterial values are displayed by those choosing instead natural burial. Meanwhile, less secure members of affluent societies, along with recent migrants to cities in developing societies, typically retain a more traditionally 'respectful,' or status-displaying, style of funeral. The status insecurity approach to theorizing funerals, common currency for decades in anthropology and archaeology (Cannon, 1989), thus has considerable potential when combined with the recent thinking about postmaterialism to help explain trends in contemporary funerals.

Bereavement

Psychological studies of bereavement have focused on what modern Western mourners feel, while anthropological studies have focused on what non-Western mourners do, especially through ritual. Reflecting this, a number of sociological studies have looked at the mourning customs of minority groups within Western societies (Kalish and Reynolds, 1981). The impression this uneven research literature gives is that traditional people's feelings are governed by cultural norms and rites, while grief for majority members of Western societies is driven by an inner, natural psychological process and is not a social phenomenon. This is despite Hochschild's (1983) sociological analysis of feeling rules in contemporary capitalism, and historical studies showing how grief norms grief have evolved and been politically manipulated in modern western countries (Jalland, 2010).

A 50-year-old book that still stands out as a beacon in this sociological research desert is Geoffrey Gorer's (1965) national representative survey of grief and mourning in Britain. Gorer identified a number of different cultural norms about grief, one of them being that it should be private, which in the 1990s got picked up in sociological debates about the public/private relationship in dying and grieving, not least in Walter (1999). That grief is governed by social norms, for example, that grief is appropriate for certain kinds of relationships or should last a certain length of time, is also central to Ken Doka's (2002) development of the concept of disenfranchised grief, which identified the circumstances in which grief might not be socially acknowledged. The concept of disenfranchisement is sociologically ambiguous, however, in that although acknowledging the normed nature of grief, it seems to imply that every kind of grief should be enfranchised, that is to say, grief should be naturally expressed and not governed by social norms. To our knowledge, however, no human society has yet managed without grief norms, and it seems unlikely that advanced capitalism's need to control both its workforce and consumers will be significantly different.

Another sociological approach to grief is to draw on the sociology of emotion (Charmaz and Milligan, 2006), and there is considerable potential for developing this.

Remembrance and Collective Memory

Psychological theories of bereavement turned in the 1990s to consider the continuing bonds between the living and the dead (Klass et al., 1996), which helped provide an intellectual climate in which sociologists could explore the 'postselves' (Kearl, 2010) that people construct for themselves in anticipation of their death or have constructed for them after death – although Unruh (1983) had already theorized this phenomenon sociologically in the early 1980s.

Public responses to high-profile deaths (AIDS, 9/11) and the dramatic sudden death of high-profile individuals (e.g., President Kennedy, Princess Diana) may temporarily recreate the solidarity of an 'imagined community' of mourners who vicariously participate in traditional ceremonies via television and the Internet. This recalls the seminal work of the French sociologist, Emile Durkheim (1995), who showed how mourning ritual reinforced the cohesiveness and core values of the social group. Exploring the dialectic of how death can both threaten the basis of society and enhance its solidarity thus continues to be a theme in the sociology of death.

The turn of the century has also witnessed a major memorial boom. Doss's (2010) analysis of memorial politics shows that collective memory is not necessarily consensual, but entails power and conflict. This understanding links the sociology of public mourning to research in collective memory, and indeed several research studies in collective memory focus on memorialization of the dead. Postmodern death seems to have come out of the private closet to which modernity arguably confined it.

Communication Technology

Many people are now using the Internet to socially relocate those who are dying, mourning, or dead (Sofka et al., 2012; Walter et al., 2011–2012). Kin spread around the world and may, through Skype, be present at an old person's hospital deathbed. Close family, left alone by modernity to grieve in private, now log in to the deceased's Facebook site where they encounter posts from a much wider penumbra of the dead person's social network. This reinsertion of the grieving individual into a community of mourning may be welcomed, as when a bereaved parent sees that the deceased's friends have not forgotten an anniversary. However, individuals grieve in different ways – ways that were invisible when grief was private but are now visible online; older kin are not always happy with what they may see as trite comments produced by the deceased's online community. Privacy protects, in death as in life; living in community can be hard work, in death as in life.

People have probably talked to the dead from time immemorial, but in much of the twentieth century such conversation was believed to be irrational, so it came to be conducted in

private, at home or at the graveside when nobody else was around, quietly under the breath, or within the very specific confines of a séance or Spiritualist church meeting. Online, however, twenty-first-century mourners address the dead in the company of other mourners, and are not criticized for so doing; indeed it has become an online convention to post messages to the dead. And unlike snail mail, the online dead often have an address (e.g., their still-extant social network site or a cyber cemetery) to which messages can be posted. Interestingly, even in secular countries such as Britain and Germany, mourners seem more likely online than offline to use spiritual language, referring to the dead as in heaven or as an angel (Jakoby and Reiser, 2013). It is as though heaven, deemed a nonplace once modern astronomy had charted the heavens, becomes plausible again – as cyberspace, a mystical, incomprehensible intermediary between here and there, between now and then, between the living and the dead. And maybe this is why the online dead tend to be addressed not as souls, cut off in heaven from the living, but as angels who maintain some kind of ongoing relationship with the living (Walter, 2011).

Abstract

The anthropology of death examines the diversity and commonalties in how human societies respond to the demise of its members. Anthropologists have documented the enormous cultural variation in the methods for disposing of the corpse, the expected behavior of the bereaved, and the ongoing relations between the living and their dead. Most cultures conceptualize death as a transition, or rite of passage, in which the fate of the corpse is linked to the ritual status of the mourners. The social impact of the death is related directly to the social status of the deceased and the type of death. The sudden, violent death of an important leader may paralyze a society, while the lingering death of a marginal stranger may pass unnoticed. Death rituals provide an opportunity to reassert core cultural values at a time of potential demoralization, and as such have important economic, political, and ideological aspects. Contemporary Western attitudes toward death, seen from a cross-cultural perspective, appear decidedly 'deviant.' Future research will focus on rituals and institutions, as well as on the impact of new technologies (medical, computer, space, etc.) on the changing conception of death.

All human cultures struggle to deal with the inevitability and mystery of death. The anthropology of death explores how human societies around the world respond to death. It is concerned with both the conceptual and organizational aspects, that is, what people believe about death and the afterlife, as well as what they actually do when faced with the crisis of death. Two main methodological approaches used are the ethnographic and the comparative. The ethnographic approach examines how single cultures cope with the demise of members, while the comparative approach tries to make sense of the enormous cultural variation in issues such as the disposing of the corpse, the expected behavior of the bereaved, and the ongoing relations between the living and their dead.

Although elaborate death rituals are probably a defining aspect of human culture, comparative studies have revealed few, if any, universal practices. Even the widespread practice of crying at a funeral is actively discouraged, for example, among the Balinese. Eating the dead (endocannibalism) is an exotic and a controversial form of disposing of the human body that was once widespread in the Amazon and Melanesia. Nevertheless, anthropologists have uncovered a number of key metaphors that help to make sense of the enormous diversity of mortuary rituals. The anthropology of death takes as its task to understand the phrase: 'All humans die,' yet in every culture, each dies in their own way.

Centrality of the Death Ritual

In most traditional cultures, death rituals stand at the center of social life. Many societies use expensive and elaborate mortuary ritual as a way of demonstrating status and power, so that the expense incurred is often an enormous financial burden. The atmosphere is not always sad or somber, but may even take on a festive atmosphere so that one may speak of 'celebrations of death' (Huntingdon and Metcalf, 1991).

The impact of the death is related directly to the social status of the deceased. Death is likely to be seen as particularly disruptive when it strikes persons who are most relevant for the functional and moral activities of the social order: "At the death of a chief, or man of high standing a true panic sweeps over the group" (Hertz, 1960 [1907], p. 76). The elaborate funeral rituals and pyramids of Ancient Egypt are outstanding examples of this ethos. Likewise, the death of a spouse often leads to a long period of taboos and restricted activity. "On the contrary, the death of a stranger, slave or child will go almost unnoticed; it will arouse no emotion, occasion no ritual" (Hertz, 1960 [1907], p. 76). In regions of high mortality, the death of an infant who is not yet considered a 'social person' may have no formal ritual or mourning. Bereaved parents often experience their loss privately, without ceremony, in what Scheper-Hughes (1992) called 'death without weeping.' In Northeast Brazil, the death of an infant or young child is often considered a blessing, in which the angel baby attains happiness in heaven. A mother's tears were actively discouraged since they would wet the angel's wings and impede the spirit-child's flight to a better place. The mothers expressed no grief but rather felt that the baby was looking after her from heaven. Scheper-Hughes' work challenges much of the received wisdom concerning the nature of grief, where such mothers would be considered as suffering pathological grief and in need of urgent intervention.

The simple funerals of some hunter-gatherers, such as the Baka Pygmies of the Central African rain forest, are notable exceptions to the widespread pattern of elaborate and complex mortuary rituals. They have no idea of an afterlife, saying "When you are gone, bang! you are gone" (Bloch and Parry, 1982).

Fieldwork Dilemmas

Death is an intensely emotional and often taboo subject, so that studying death raises special dilemmas and emotional challenges for the fieldworker (Palgi and Abramovitch, 1984). In many Western cultures, death and mourning is a time of heightened privacy. The entry into the mourner's space at such times is considered intrusive and inappropriate. Yet the ethnographic imperative demands researching even such acute grief. How fieldworkers manage their own culture's attitude toward death may be considered a case of 'ethnographic countertransference.' One explicit and early example was

described by Hortense Powdermaker, who worked in a matrilineal society in New Ireland. Powdermaker described her own extreme distress when she began taking fieldnotes at her first funeral. She imagined how intrusive such an ethnographic presence would be in her own house of mourning. She, however, discovered to her great surprise that these illiterate people felt no such intrusions, but rather that her writing added prestige to the ritual. They demanded her presence at every subsequent funeral, even long after she had constructed a complete account of the funeral process (Palgi and Abramovitch, 1984).

Many ethnographers have discussed the emotional strain of participating closely in the grief of others (Woodthorpe, 2007). Perhaps, the most moving account is by Rosaldo (2004) who connects how his overwhelming grief at the accidental death of his wife (also an eminent anthropologist) helped him understand more deeply headhunter's rage of the Ilongot in the Philippines. Rosaldo criticized the discipline's focus on death ritual, with its formality and routine, in a way that marginalizes the intense and raw feelings that often accompany actual grief. Similarly, Fabian (1973) argued that anthropologists avoid the intimate encounter with death by focusing on 'how others die.'

Death as an Event vs Death as a Process

In the West, despite recent legal and medical controversies, death is considered as occurring at a specific identifiable moment, symbolized by the 'time of death' on the death certificate. This 'punctual view of death' (Bloch, 1988) in which a person is thus either alive or dead is not shared by many cultures. Physiological demise and social death do not necessarily coincide. Instead, death is seen as part of a long, complex, and even dangerous process, with no sharp boundary between life and death. Cultures express the degree of alive–dead using different metaphors. The Merina of Madagascar, for example, use the image of wet–dry to indicate degrees of alive–dead. A newborn infant is very wet and thus very alive; in contrast, a shriveled elderly person, almost totally dry, is mostly dead. The process of drying, and hence dying, will be only completed long after biological death when the bones are dug up and placed in communal tombs (Bloch and Parry, 1982). Among Sa'dan Toraja of Indonesia, a dying person has the ability to 'see everything' but is not considered dead until the first sacrifice of mortuary rites have taken place (Tsinntjilonis, 2007).

Theoretical Approaches and Key Metaphors

"Few areas of contemporary anthropological inquiry are still so dominated by *fin de siècle* thinking as is the study of death and mortuary ritual" (Palgi and Abramovitch, 1984, p. 387). The three traditional paradigms are French sociological school (Durkheim, Hertz), early British functionalists (Malinowski, Radcliffe-Brown), and 'rite of passage' approach (Van Gennep).

Hertz's Analysis of First and Second Funerals

The single most influential text in the anthropology of death was written by a brilliant disciple of Durkheim, Robert Hertz, who was killed on the battlefield of Verdun in World War I. Many of the central ideas in the anthropology of death: That death is widely perceived as a process and not as an instantaneous event, that death is the starting point of a ceremonial process whereby a dead person becomes an ancestor, and that death is akin to an initiation into a social afterlife and hence resembles a kind of rebirth, all derive from his seminal monograph (Hertz, 1960 [1907]). His study focused on the widespread custom of second funeral, or more correctly, secondary treatment of the remains. One of the main ideological reasons for a double ceremony, often separated by years, has to do with the dual nature of the person as composed of both body and spirit (or soul). Dead bodies or corpses are usually associated with ritual pollution and sorrow. The first funeral, in a literal and symbolic sense seeks to get rid of these polluting and sorrowful aspects. The second funeral is focused on the initiation of dead people's spirits into the realm of the ancestors, where they will continue to serve as a cultural resource, watching over and guiding the living. This structuralist perspective highlighted parallels between the decomposition of the corpse and the fate of the soul.

Death Rituals and Core Values

In many societies, the occurrence of a death disrupts social life severely, so that "it is stricken in the very principle of its life in the faith it has in itself" (Hertz, 1960 [1907], p. 78). A functionalist perspective stressed how mortuary rites served to resolve the disruptive tendencies that operate at times of social crisis. Malinowski demonstrated how ceremonies counteract the centrifugal forces of fear, dismay, and demoralization associated with death, and provide a powerful means of reintegration of the group's shaken morale (Palgi and Abramovitch, 1984). These rituals must provide an answer to the meaning of life for the community at a time when it is most threatened. As a result, the study of such death rituals provides a unique opportunity for studying the core values of any culture. The functionalist perspective emphasized the problem of death for society, and especially the issues of inheritance, redistribution of rights, and statuses, as well as the reintegration of mourners into day-to-day life.

Death as a Journey or Rite of Passage

Most cultures conceptualize death as a transition or rite of passage. In many cultures, this transition is seen as a journey to an ultimate destination that may culminate in rebirth, ancestral abode, reunion with nature or divinity, or indeed total oblivion. Death rituals, like all rites of passage, have a three-part structure, first delineated by Van Gennep: separation, liminality, and reincorporation (Huntingdon and Metcalf, 1991). The spirits of dead people must be separated from their social roles as members in the community of the living and enter an undefined 'in-between' state, finally being reincorporated into a new status as the end of the 'journey.' Often, the fate of the soul is modeled on the fate of the body. Just as the soul of the deceased is formless and repulsive, as in Borneo when the dead are left to ferment in large jars, so the soul of the deceased is seen as homeless and

the object of dread. Only when the bones alone are left can the ritual journey be completed (Huntingdon and Metcalf, 1991). Likewise, the ritual status of the mourners is in turn linked to the fate of the corpse in its process of decay, and the soul in its progress on its journey. Some cultures do have a specific tie-breaking ritual, which symbolizes both the end of mourning for the bereaved, and the end of the journey for the soul or spirit of the deceased. The living are often required to nurture the deceased at each stage along the journey through the afterlife and this conception helps to explain why the dead take up so many economic, emotional, and spiritual resources.

The Danger of the Unincorporated Dead

From this rite of passage perspective, it is possible to understand why the unincorporated dead, trapped permanently in the liminal realm, are often considered as dangerous. These wandering spirits, for whom no rites were performed, may act as hungry ghosts. They yearn to be reincorporated into the world of the living. Since they cannot be, they behave like hostile strangers who consequently must find sustenance at the expense of the living. Many cultures use elaborate strategies to confuse the spirit of the deceased so that it will not return to the realm of the living. Illness, misfortune, and associated healing rituals are often attempts to incorporate these lost souls. The 'Tomb of the Unknown Soldier' in modern states provides a resting-place for unincorporated spirits of the war dead.

Parallels to Other Life Cycle Rituals

Anthropologists have also noticed how death rituals often parallel other life cycle rituals, notably births and weddings. Conceptually, death is often seen as a rebirth into another world, while birth is viewed as the literal rebirth of a deceased ancestor. Likewise, for weddings, just as a bride may leave her family, so too the soul of the deceased departs for another world. In rural Greece, for example, the same lyrics are sung at both weddings and funerals (Danforth, 1982).

Emotional Response of the Mourners

The comparative study of how mourners respond to loss and bereavement has attracted considerable attention (Parkes et al., 1997). Almost all cultures allow, or even encourage, the expression of crying, as well as fear and anger by mourners. Women tend to cry and self-mutilate, while men express anger, or direct aggression away from themselves. Yet most societies have developed mechanisms and institutions to control the anger of the bereaved, especially via the use of ritual experts (Rosenblatt et al., 1976). In many cultures, there is no cultural category of a 'natural death'; rather, each death is akin to murder in which a culturally sanctioned cause of death must be uncovered. Almost all societies concern themselves with the spirits of the dead that probably give expression both to the 'unfinished business' between the living and the dead, and the fact that death does not end a relationship. The more complicated the relationship and unfinished business in which the dead are dispossessed in favor of the living, the greater will be the dread and concern about ghosts.

Good Death vs Bad Death

Recent interest has focused on cultures' conception of what constitutes a 'good death' or a 'bad death' (Aries, 1974; Humphreys and King, 1981). A good death represents a cultural ideal that enacts a symbolic victory over death and the regeneration of life (Bloch and Parry, 1982). A bad death does the opposite, leaving survivors despairing, helpless in the face of meaninglessness, evil, or nothingness. Unpredictability, violence, or intentional harm are widespread attributes of a bad death. Archetypal examples of bad death include suicide, homicide, and death in a traffic accident. A good death is the mirror image of a bad death: An expected, painless death of an elderly individual with a multitude of descendants in attendance. Jewish Talmud compares a good death to the ease of plucking a hair from a bowl of milk and a bad death to the interminable agony of pulling wool from off a thorn bush. But a good death has culture-specific aspects, such as the setting, timing, physical posture, thoughts, and actions at the final moment, and other 'near death experiences,' as well as a preferred cause and manner of death (Abramovitch, 1999). A Hindu should die in the open air, as an act of self-sacrifice, abandoning life to the sound of the chanting of the names of God, for his thoughts at that moment may determine his subsequent fate and rebirth. A reluctance to die at the appropriate time may lead to the death of a young relative in his place (Parry, 1994).

Controversies Over the Beginning and End of Life

Controversies at the beginning and the end of life over abortion, organ donation, and brain death may be analyzed in anthropological terms (Kaufman and Morgan, 2005). The disagreement may be understood as revolving around conflicts concerning the nature of the 'social person.' Each society has different criteria for when an infant becomes a fully human, social person. For example, among Kaliai people of West New Britain, the key distinction is the child's ability to discuss dreams. Children who are unable to do so, will not have death ritual should they die; but dream tellers will (Counts and Counts, 2004). Opponents of abortion identify conception itself as signaling the onset of the social person giving the fetus inalienable rights to life and protection. Supporters of abortion, in contrast, regard the fetus as a part of the woman's body that only becomes social person at birth. Similarly, proponents of brain death and organ transplants identify a social person largely with cognitive function; when that is lost, the person is gone forever and the organs may be harvested. In contrast, in Japan, which long resisted organ transplantation, rejected brain death criteria for death since traditionally they believe that a person's life spirit is diffused throughout the body. The first Japanese surgeon to attempt a transplant, using brain death criteria, was charged with murder. In a different context, Japanese women will often make special ritual offerings to fetal spirits following an abortion.

Changes in Mortuary Ritual

Mortuary rituals have long been considered as one of the most stable aspects of a culture. Recent research has challenged this view. Change may occur rapidly altering the tradition

of millennia. One dramatic case concerns South Korea (Park, 2010a, b). Until the 1980s, death and funerals took place at home, in private ceremony in the family garden (*mandang*), followed by burial in an auspicious site that was consulted in times of misfortune. Cremation was a social taboo that was identified with the Japanese occupiers. In the last decades, traditional burial has almost disappeared. Funerals are held in hospital or private funeral halls, followed by public cremation with the ashes lodged in columbarium or scattered beneath trees in a memorial park. The severe shortage of land for cemeteries, change in design of housing, government policy all played a role in the change, as it did in the rapid introduction of wall burial in Israel.

Future Directions

The anthropology of death traditionally focused narrowly on the death of single individuals in small-scale societies. Future research, in contrast, will need to investigate how local cultural traditions interact with the wider collective and global context. The study of mass death, in the form of epidemics, natural disasters, or political violence, provides one stimulating area of investigation (Robben, 2004b). The diverse impact of new technologies may provide another intriguing area for understanding how conceptions of death are changing. Web pages on the Internet provide for new forms of commemorating the dead. Organ donation allows a 'bad death' to be transformed into a 'good death' as a posthumous act of self-sacrifice. Cloning awakens in some the 'myth of eternal life'; while artificial life support has created a new state in which persons are neither alive nor dead.

Death will always remain a mystery, but the cross-cultural investigation of death will continue to provide unexpected insights into how humans cope with that mystery.

Abstract

Death penalty is the deliberate taking of human life as state-sanctioned punishment. In recent years, a majority of the world's countries have further restricted or abolished executions all together. Abolition of the death penalty in many countries has occurred in a context of momentous political, social, and legal changes. Newly established nations have embraced abolition, moreover, because powerful European institutions (e.g., the European Union) have made abolition a requirement for membership. At the same time, the European campaign has been less successful in China – the world's far and away leading executioner. China's complex politicolegal structure makes death penalty abolition exceedingly difficult.

Introduction

There are currently 58 countries worldwide that retain the death penalty both in law and in practice (Bohm, 2013). Of these, only two – the United States and Japan – are members of the Organisation for Economic Cooperation and Development, the body that represents the world's 36 industrialized nations (Bohm, 2013; Organisation for Economic Cooperation and Development, n.d.), and only 21 conducted an execution in 2012 (Amnesty International, 2013). At one time, the use of the death penalty was widespread, but the practice began to fall into disfavor in the final quarter of the twentieth century as nations began to recognize and emphasize human rights, especially in Europe. Article 5 of the United Nations *Universal Declaration on Human Rights*, which was ratified in 1948, bars the use of 'cruel, inhuman or degrading treatment or punishment,' and in recent years, majority world sentiment has generally concluded that the punishment of death is cruel and degrading.

This article addresses this momentous change in death penalty support from a global perspective. We begin with a discussion of the theoretical justifications for the death penalty, the origins of the death penalty, and its proliferation and subsequent abolition in most of the world's nations. We will then take a more in-depth look at the two retentionist countries: the United States and China. These case studies point to important directions for future research on death penalty abolition and highlight the limitations of privileging one perspective – international, national, or local – over the other (Miao, 2013).

Justifications for the Death Penalty

There are three primary theoretical justifications for the penalty of death: retribution, incapacitation, and deterrence. The idea of retribution is that the offender deserves to die because he or she has harmed society in some way and must sacrifice his or her life to compensate for this harm. He or she owes society a debt; the crime of murder deserves the penalty as just deserts for the pain and suffering caused to the victim(s). The theory of incapacitation is based on the goal of physically preventing offenders from committing future criminal acts. The ultimate incapacitation, therefore, is death. By killing those who have killed, we render them unable to prey upon and kill anyone else. In fact, there is evidence from a program of empirical research from the United States called the Capital Jury Project (Bowers, 1995) that capital jurors use this type of vicarious self-defense to justify their death verdicts. The less time that jurors think a capital defendant not sentenced to death will spend in prison before being released, the more likely they are to vote for death (Bowers and Steiner, 1999). Moreover, jurors who believe that the defendant will be dangerousness in the future are predisposed to vote for death (Vartkessian, 2012). Last, the theory of deterrence suggests that humans are essentially rational actors who weigh the costs and benefits of performing an action. By making the punishment for murder severe enough, people can be convinced not to kill out of fear of being killed themselves. This justification for the death penalty has received the most scholarly attention in the United States. However, an extraordinarily detailed review of more than three decades of deterrence studies of capital punishment in the United States seriously challenges the validity of this body of research as a whole and thereby any empirical claim that the death penalty deters murderers (Nagin and Pepper, 2012).

Historical Context: Reach, Retention, and Rejection

Hood and Hoyle (2008) and William Schabas (2002) have published the most detailed historical and empirical assessments of the death penalty from a global perspective. The purpose of this section is then to briefly highlight the most enduring themes in the use of the death penalty worldwide – namely, its reach, retention, and rejection. Beginning with the Ancient Laws of China, the death penalty was established as a punishment for numerous crimes. In the eighteenth-century BC, the Code of King Hammurabi of Babylon listed over 20 different crimes as punishable by death (Slanski, 2013). Adultery, harboring escaped slaves, and robbery were all punishable by death under the Code but murder was not. The Bible first codified the death penalty's reach as extending to

murder as well as a wide array of offenses such as violation of the Sabbath, adultery, homosexuality, incest, and rape, among dozens of other offenses. The first documented narrowing of crimes punishable by death occurred under Jewish Talmudic Law. Some rabbis called for its very limited use and some even called for abolition (Erez, 1981).

The death penalty had its most unprecedented and brutal expansion during the Middle Ages. Not only were the number of death-eligible crimes expanded but executions were invariably accompanied by torture. A woman convicted of high treason was burned alive and men were hanged or drawn and quartered. In terms of documented numbers, a high water mark for executions may very well have been under the reign of Henry VIII. It is estimated that at this time an astonishing 72 000 executions occurred (Randa, 1997).

Early into the Enlightenment period, Montesquieu was one of the first proponents of limiting the death penalty to murder. However, the modern abolition movement did not begin until Cesare Beccaria published *On Crimes and Punishments*. This revolutionary legal treatise had an enormous influence on legal systems across the globe. In the United States, for example, Pennsylvania adopted degrees of murder with one singular objective: to limit the death penalty's reach (Bedau, 1998). Many other jurisdictions in the Northern United States eliminated the death penalty for rape, robbery, burglary, and arson. By 1860, only treason and murder were death-eligible crimes. Only 4 years later, Michigan became the first US state to abolish the death penalty permanently. The Southern states also limited the number of capital crimes for whites but maintained the death penalty for numerous crimes for both free and enslaved blacks. Under the region's infamous 'Black Codes,' blacks could be executed for offenses such as rebellion, arson, burglary, and assaulting a white woman (Higginbotham, 1980).

In 1863, Venezuela became the first nation in the world to abolish the death penalty; the tiny Republic of San Marino in Southern Europe became the second in 1865. Numerous Latin American nations followed suit in the late nineteenth and the early twentieth centuries, including Costa Rica, Brazil, Ecuador, Uruguay, Colombia, and Panama (Bohm, 2013; Schabas, 2002). However, any momentum toward abolition came to a screeching halt with the rise of totalitarianism, specifically the rise of Nazi Germany. The Nuremberg war crimes tribunals would document Hitler and the Nazi regime's insatiable appetite for the death penalty. In the genocidal aftermath of the Second World War, criticism of the death penalty by human rights experts was a pivotal moment for an already galvanized international abolition movement. In the years leading up to 10 December 1948, the historic date when the United Nations General Assembly adopted the *Universal Declaration of Human Rights*, the abuse of the death penalty was of primary concern. However, the death penalty for Nazi war criminals was authorized as an exception. Continued retention for the so-called most atrocious crimes would be the primary "dialectic that confronted those who first proclaimed, in international law, a 'right to life'" (Schabas, 2002: p. 6).

If the death penalty for the most atrocious crimes created exceptions even in the midst of evidence of extraordinary abuses, then it is not surprising that a majority of countries retained it, at least in some form, for many decades after World War II. Only six nations – Germany, Honduras, Monaco, Dominican Republic, Austria, and Vatican City – abolished the death penalty between the end of World War II and 1970 (Bohm, 2013). However, only a few decades later, the tide would dramatically turn. Indeed, by the twenty-first century, a once historically elusive international consensus against the death penalty became a reality (Hood and Hoyle, 2008).

Rejecting the Death Penalty: A New Global Majority

The final quarter of the twentieth century and the early part of the twenty-first century saw rapid acceleration in the number of abolitionist countries. By the beginning of 1980, only 20 countries had abolished the death penalty, but by the beginning of 2013, this number had nearly *quintupled* – 97 nations had abolished the death penalty for all crimes and a total of 140 nations had ceased conducting executions for at least 10 years (Bohm, 2013). Perhaps the most compelling explanation for this radical decline has been the assimilation of international human rights norms calling for the worldwide abolition of the death penalty as prerequisite for membership to the Council of Europe and the European Union. Given the recent adoption of democratic constitutions and capitalist imperatives in former Eastern and Soviet Bloc nations, membership in these powerful institutions has been an important catalyst for widespread abolition. As Hood and Hoyle (2008: p. 25) explain, quoting the Parliamentary Assembly of the Council of Europe:

> Fundamentally important was the message that had been conveyed: a *principled* (emphasis in original) opposition to the death penalty as a violation of fundamental human rights. Both the Council of Europe and the European Union have declared that 'the death penalty has no legitimate place in the penal systems of modern civilized societies, and its application may well be compared with torture and be seen as a inhuman and degrading punishment.' The language is uncompromising.

Beyond a commitment to abolition as a membership requirement, the European Union has also engaged in aggressive diplomatic efforts with retentionist countries to abolish the death penalty. The European Union has, moreover, funded training for anti–death penalty lawyers and policy makers and has promoted empirical research to study the administration of the death penalty in retentionist countries. In South America and Mexico, the path to abolition has stemmed from a combination of factors, including the fall of authoritarian regimes, rise of antideath penalty religious imperatives, and the creation of national penitentiary systems (Hood and Hoyle, 2008: p. 62).

Retaining the Death Penalty: A New Global Minority

A total of 58 countries – less than a third of the world's nations – retains the death penalty in practice. A majority of these nations are located in Africa, the Middle East, the Caribbean, and Southern Asia. Only one European nation

(Belarus), one South American country (Guyana), and one North American country (the United States) retain the death penalty (Bohm, 2013), and only two retentionist nations – the United States and Japan – are industrialized. When looking at actual executions, the numbers get even more concentrated. Only 21 nations carried out an execution in 2012. China continues to be far and away the world's leading executioner. Although no official data exist, Amnesty International (2013) surmises that China executes thousands of people every year. The reach of its death penalty today cannot be underestimated: "China is only a single entry in the 197-nation scorecard for recording death penalty status, but estimates since the 1990s suggest it probably accounted for *more than 90%* (emphasis added) of executions worldwide during that period" (Johnson and Zimring, 2009: p. 10).

United States

To claim that the United States is a retentionist nation is slightly misleading. Although there were 39 executions in 2013 and 77 death sentences imposed in 2012, bringing the total number of persons on death row in the United States to 3108, the number of death sentences and executions has been in steady decline. While there was a high of 315 death sentences in 1996 and 98 executions in 1999 (Death Penalty Information Center, 2013), the number of death sentences imposed today is at an all-time low (Liebman and Clarke, 2011; Fleury-Steiner et al., forthcoming). Furthermore, 18 of the 50 states in the United States have abolished the death penalty and two more states have not executed anyone since the Supreme Court lifted a nationwide death penalty moratorium in 1976. Three US states – Texas, Virginia, and Oklahoma – account for the majority of executions carried out since 1976 (Bohm, 2013) and 85% of American counties have not been responsible for a single execution since 1976 (Dieter, 2013). In other words, it can be concluded that the death penalty as practiced in the United States today is a phenomenon confined to a decidedly *localized* minority (Liebman and Clarke, 2011).

A closer look at the United States' death penalty as a phenomenon carried out by a small minority of locales is quite revealing. About 15% of US counties account for all executions carried out since 1976, and a miniscule 2% of the nation's more than 3000 counties account for a majority of its executions (Dieter, 2013). Extensive empirical research documents that prosecutors in these locales are more likely to seek death sentences and more likely to find juries willing to impose death sentences (Berk et al., 2005; Paternoster et al., 2003; Poveda, 2006; Pierce and Radelet, 2005). In other words, who gets sentenced to death is more a function of *where* the crime is committed than a function of the facts of the case. But why these counties? For example, one explanation for the dramatic recent spike in death sentences in New Castle County, Delaware, is the sweeping change to the death penalty process that makes a death sentence far more likely to be imposed. Specifically, since 1991, jurors act only in an advisory role in death penalty cases – a move that caused the number of death sentences and executions in the state to skyrocket (Johnson et al., 2012). Importantly, this change to Delaware's death penalty scheme was catalyzed by a racially charged incident involving four black men who escaped execution for the robbery–murder of two white armored car guards after a single juror refused to vote for a death sentence (Fleury-Steiner et al., 2009). Recent empirical research on Delaware death penalty jurors suggests that this 'advisory' role leads capital jurors to describe themselves as less responsible for imposing the death sentence (Kleinstuber, 2013a) and to give only very cursory evaluations of mitigating evidence (Kleinstuber, 2013b).

More recent studies have used county-level data to confirm the centrality of race in maintaining the death penalty. According to Poveda (2006), counties with more black residents and a long tradition of executions are more likely to sentence people to death and more likely to execute them. Liebman and Clarke (2011) have, moreover, concluded that these counties are more insular and thus are characterized by a more visceral fear of nonwhite outsiders. Indeed, Fleury-Steiner et al. (forthcoming: p. 3) argue that these aggressive death penalty locales are driven by 'an enduring local defense of racial boundaries.'

Despite the few remaining active death penalty locales in the United States, its recent decline nationally cannot be underestimated. In the wake of a myriad of scandals, including the imposition of erroneous death sentences (Gould, 2009) and even wrongful executions in Texas (Liebman et al., 2012), it appears that the United States' appetite for the death penalty has diminished greatly and it is moving in the same direction as the majority of the world's nations. Indeed, six states have abolished the death penalty since 2007 and, as of this writing, numerous others are debating abolition. The US Supreme Court has also recently narrowed the scope of who is eligible to be sentenced to death and in the process, relied upon numerous foreign legal judgments (Dennington, 2006). In 2002, the Court outlawed the execution of the mentally challenged, noting that 'the world community … overwhelmingly disapprove[s]' of the execution of mentally challenged offenders (Atkins v. Virginia, 2002: p. 316, n. 21), and in 2005, it barred the use of the death penalty for offenders who were under the age of 18 years at the time of the crime; the decision noted that the United States was the only nation in the world still permitting juvenile executions (Roper v. Simmons, 2005).

China

According to Miao (2013), the use of the death penalty in modern China may be divided into three relevant periods: the first three decades (1949–79), the Strike Hard era (1980–2003), and the Hu-Wen era (2004–12). The high water mark for executions occurred in this first period under Mao Zedong. Drawing on historical records located in Beijing's Central Press of Historical Records, Miao (2013: p. 3) estimates that a massive 3-year (1950–53) crackdown on counterrevolutionaries resulted in approximately 710 000 executions. Over the next three decades, the country experienced a marked decline in executions. As the country began to adopt capitalist market-based reforms in the 1970s, a pronounced fear of disorder led to the now infamous "Strike Hard" Campaigns. While this period resulted in significantly fewer executions than under Mao Zedong, "approximately 24 000 offenders were sentenced to death and around 1 027 000 were convicted of criminal offences" (Miao, 2013: p. 4). China's postcounter revolutionary

history of state-sanctioned executions occurred in a conflicted politicolegal landscape:

> This pattern of ebb and flow in the past can be explained partly by the constant tension between a utilitarian view that the death penalty is an expedient instrument to achieve short-term political goals and a stricter adherence to the rule of law, penal regulation, and due process when dealing with capital cases. In the most recent Hu-Wen era, such an uneasy relationship in penal ideology takes the form of contradictions between the populist impulses of revenge and retribution and a serious commitment to restrain and civilize the use of capital punishment. (Miao, 2013: p. 4)

Similar to strong popular sentiment that has driven pro-death penalty activity in US locales (Simon and Spaulding, 1998), a robust 'penal populism' (Roberts et al., 2003) seems to be present in China today. In response, in 2010, China adopted *Rules to Exclude Illegal Evidence in Criminal Cases* and *Guidelines to Scrutinize and Analyse Evidence in Capital Cases*, the country's first formal attempts to provide defendants in death penalty cases due process protections. By early 2011, China's President, borrowing from the US Constitution's restriction on cruel and unusual punishment, ordered the country's legal system to adopt its own regulations, *The Eighth Amendment to the Criminal Law*. This new law proposed unprecedented steps to shorten the reach of executions by formally limiting the number crimes punishable by death and by narrowing the death eligibility of defendants over the age of 75 years. In a move doubtlessly inspired by the United States, the President also proposed the goal of adopting lethal injection over shooting as the preferred method of execution.

Recent empirical research involving interviews with 18 national and 18 local legal elites closely involved in the administration of the death penalty in China suggests that these reforms have been slow to take hold in practice (Miao, 2013). On the one hand, it appears as though most national and local-level legal elites support greater regulation of China's death penalty, but these reformist sentiments have not translated into institutional reform on the ground. For one, China's top-down reforms have been largely symbolic. Similar to active death penalty locales in the United States (Bright and Sanneh, 2013), the resources needed to enforce greater regulation at the local level – where death sentences and executions take place – have not been provided. Moreover, there has been resistance to death penalty reform by a majority of Chinese lower level judges and government officials. One of the provincial court judges Miao interviewed also expressed fear of overturning death sentences as betraying the wishes of victims' families and catalyzing public suicides and rioting if the reforms of national legal elites were put into practice: "If I sentence someone to death, my verdict may be overturned. It is easier for the people 'at the top' to talk; but it is us who are stuck in a position between the devil and deep blue sea" (quoted in Miao, 2013: p. 11).

Conclusion

Overall, the European influence on global abolition cannot be underestimated. A majority of countries have either dramatically curtailed the use of executions or banned them altogether. However, Asia has been far less receptive to such efforts (Johnson and Zimring, 2009). The limits of international human rights campaigns seem, at least as of this writing, to have been largely symbolic in China. Indeed, despite its very recent adoption of European-inspired reforms intended to limit the reach of its death penalty, thousands of executions are carried out annually in Chinese provinces in secret (Amnesty International, 2013). Although China has made significant efforts at the national level to limit the use of the death penalty, national elites have not provided needed resources to realize such reforms at the local level. Local elites have, moreover, steadfastly resisted such attempts at systemic change. In this way, future empirical research on China's death penalty generally and other death penalty retentionist countries in particular must "take into consideration a complex web of interactions between actors at the international, national and lower levels" (Miao, 2013: p. 16). Attending to jurisdictional complexity and institutional dynamism is clearly important for future research. Any assessment of a nation's future with the death penalty must attend to the particularities (e.g., politics, legal structures, and religious beliefs) of the death penalty as it is carried out on the ground.

Decision and Choice: Bounded Rationality

Roy Radner, Stern School of Business, New York University, NY, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The 'Savage paradigm' of rational decision-making under uncertainty has become the dominant model of human behavior in mainstream economics and game theory. 'Bounded rationality' refers to the study of how human decision-makers deal with their cognitive limitations that may prevent them from fully applying the Savage paradigm to real problems without entirely abandoning the notion of rationality. This article sketches the historical roots and current developments of this topic, distinguishing between attempts to extend the Savage paradigm ('costly rationality') and the development of more radical departures.

Introduction

Some kind of model of rational decision-making is at the base of most current economic analysis, especially in microeconomics and the economics of organization. Such models typically assume that economic decision-makers have sufficient cognitive capacities to solve the problems they face, and have preferences and beliefs that are consistent in a rather strong sense. In particular, it is typically assumed that decision-makers (1) do not make logical errors, and can solve any relevant mathematical problems; (2) can process all available information in the time required (including computation, storage, and retrieval); and (3) have an adequate understanding of the decision problems they face, which includes having precise beliefs about the relevant uncertainties and precise preferences among the various consequences of their actions. The economic agent described by such models is sometimes stereotyped by title *homo economicus*.

However, this model has been criticized as inadequate from both normative and descriptive viewpoints. Some strands of this critical movement form the topic known as 'bounded rationality.' This article sketches the historical roots and some current developments of this topic, distinguishing between attempts to extend the standard models and the need for more radical departures. Other strands have been grouped under the topic of behavioral economics, which typically goes beyond assumptions of rationality in economic behavior (*see* Behavioral Economics).

Unease with mainstream models of *homo economicus* was already voiced by J.M. Clark (1918) at the beginning of the twentieth century (see Radner, 2000, p. 631), but the work of Jacob Marschak and Herbert Simon provided the stimuli for a more intense level of activity. The term 'bounded rationality' was coined by Simon:

> Theories that incorporate constraints on the information-processing capabilities of the actor may be called *theories of bounded rationality*. (Simon, 1972, p. 162)

(For a review of empirical evidence of bounded rationality, see Conlisk, 1996.)

The current mainstream theory of rational individual decision-making in the face of uncertainty was elaborated by Savage (1954). This will be called here the *Savage paradigm*, and will be the main starting point of this article. Extensions of this theory to describe rational strategic behavior in multiperson situations are the subject of the *theory of games* (discussed later). The notion of *optimizing* is central to all of these models of rationality.

The general concept of *bounded rationality* covers the two rather different approaches of Marschak and Simon. Marschak emphasized that the Savage paradigm could be extended to take account of costs and constraints associated with information acquisition and processing in organizations, without abandoning the notion of optimizing behavior. This approach will be called here *costly rationality*, and is elaborated later in the section Costly Rationality and the Extended Savage Paradigm.

Simon was also concerned with behavior that could not so easily be interpreted, if at all, as optimizing. However, he retained a focus on the notion of 'rationality.' One might paraphrase his study of bounded rationality as 'How do smart people deal with their cognitive limitations?'; this, until further notice, will be the interpretation of this term that is adopted in this article (see section Bounded Rationality).

However, Simon never gave a precise definition of 'smart people.' Recently, even further departures from the Savage paradigm have received increasing attention in the literature, abandoning to some extent the concept of rationality altogether, under the heading 'behavioral economics.' This topic will not be treated here, but see the entry Behavioral Economics.

Uncertainty

Discussions of rational decision-making – unbounded and otherwise – have been closely tied to uncertainty. The very beginnings of formal probability theory were in part stimulated by questions of how to act rationally in playing games of chance with cards and dice. During the first half of the twentieth century, a number of alternative views were developed concerning the nature of uncertainty, the possibly different kinds of uncertainty, and whether, or in what circumstances, it could be measured (Arrow, 1951; Savage, 1954; Chapter 4). One could be uncertain about natural events, the consequences of action, the laws of Nature, or the truth of mathematical propositions. There was general

(but not universal) agreement that, if uncertainty could be measured (quantified), then that quantification should obey the mathematical laws of probability. However, the 'frequentist school' reserved the legitimacy of probabilistic reasoning for 'experiments' (planned or naturally occurring) that were repeated indefinitely under identical conditions. The 'personalist school,' which included a diverse set of methodologies, argued that the concept of probability was applicable to events outside of the frequentist realm. Some personalists went so far as to deny that the frequentist view could be applied meaningfully to any events at all, that is, that all probability judgments were 'personal' (see Arrow's, 1951 and Savage's, 1954, Chapter 4, accounts of the work of Ramsey, Keynes, Jeffries, Carnap, and de Finetti). In some sense, the personalist view might also be ascribed to earlier authors, such as Bayes and Laplace. The personalist view was given a solid foundation by Savage (1954).

Central to the development of thinking about uncertainty was the simple idea that uncertainty about the consequences of an action could (or should) be traced to uncertainty about the 'state of the world' in which the action would be taken. An essential feature of the concept of the state of the world is that it is beyond the control of the decision-maker in question. A further clarification was provided by the *theory of games* (put forward by J. von Neumann and O. Morgenstern in 1944, and further elaborated by J. Nash, J. Harsanyi, R. Selten, and others). In multiperson decision-making situations in which the participants have conflicting goals, this theory distinguishes between two aspects of the state of the world from the point of view of any single decision-maker, namely (1) the 'state of nature,' which is beyond the control of any of the persons involved, and (2) the actions of the other persons, the latter being called 'strategic uncertainty.' (For material on the theory of games, especially noncooperative games, see Game Theory; Noncooperative Games; Game Theory: Relation to Bayesian Theory.)

The remainder of this article concentrates on a critique of the theory of rational behavior as it is applied to single-person decision-making, or to multiperson situations in which the persons do not have conflicting goals. (For discussions of bounded rationality in a game-theory context, see Rubinstein, 1998; Radner, 2000.)

The Savage Paradigm

A sketch of the Savage paradigm is needed here in order to understand the notions of costly and bounded rationality. (For a systematic treatment, see Utility and Subjective Probability: Contemporary Theories.) The essential building blocks of the model are (1) a set of alternative *states of the world*, or simply *states*, which are beyond the decision-maker's control; (2) a set of alternative actions available to the decision-maker, or as Savage calls them, *acts*; and (3) a set of alternative *consequences*. An act determines which consequence will be realized in each state (of the world). Hence a parsimonious way to think about an act is that it is a function from states to consequences.

The decision-maker (DM) is assumed to have preferences among acts. These preferences reflect both the DM's *beliefs* about the relative likelihood of the different states, and the DM's *tastes* with regard to consequences. A few axioms about the independence of beliefs from consequences enables one to impute to the DM two scales: (1) a *probability measure* on the set of states, reflecting the DM's beliefs; and (2) a *utility scale* on the set of consequences, reflecting the DM's tastes. Using these two scales, one can calculate an *expected utility* for each act, in the usual way, since an act associates a consequence with each state. Thus for each state one calculates the product of its probability times the utility of the associated consequence, and then adds all of the products to obtain the expected utility of the act. One proves that expected utility represents the DM's preferences among acts in the following sense: *the DM prefers one act to another if and only if the first act has a higher expected utility*. (This theorem is sometimes called the *Expected Utility Hypothesis*.) The *rational* DM is assumed (or advised) to choose an act that is most preferred among the available ones, that is, has the highest expected utility; this is the assumption of *optimization*.

The simplicity of this formulation hides a wealth of possible interpretations and potential complexities. First, the axioms of the theory enable the DM to infer preferences among complicated acts from those among simpler ones. Nevertheless, the required computations may be quite onerous, even with the aid of a computer.

Second, if the decision problem has any dynamic aspects, then states can be quite complex. In fact, a full description of any particular state will typically require a full description of the *entire history* of those features of the DM's environment that are relevant to the decision problem at hand.

Third, the description of the set of available acts reveals, if only implicitly, the opportunities for the DM to acquire information about the state of the world and react to it. The laws of conditional probability then determine how the DM should learn from observation and experience. *In fact, this is what gives the Savage paradigm its real 'bite.'* An act that describes how the DM acquires information and reacts to it dynamically is sometimes called a *strategy* (plan, policy). In a model of a sequential decision problem, the space of available strategies can, of course, be enormous and complex. This observation will be a dominant motif in what follows.

The formula for learning from observation is sometimes called *Bayes's theorem*, named after the eighteenth century author, Rev. Thomas Bayes. Hence, the method of inference prescribed by the Savage paradigm is called *Bayesian learning*.

Bayesian learning has an important property in a situation that can be informally described as a sequence of independent experiments carried out under 'identical' conditions an indefinitely large (strictly infinite) number of times. Suppose that in each repetition of the experiment the outcome is uncertain, and its probability distribution depends on the values of some parameters, which are also uncertain. Let the set of states of Nature be partitioned into subsets, such that to each element of the partition corresponds a specification of the parameter values. For example, each experiment consists of a single toss of a (not necessarily fair) coin, with a probability p of the outcome 'heads,' and the parameter p has the same value in all of the experiments. Each element of the partition in question, say $B(p)$, corresponds to a specific value of p. The experimenter begins the sequence of experiments with particular beliefs about p, which we shall call the 'prior distribution' of p, and

after each successive toss of the coin uses Bayes's rule to update the experimenter's beliefs about p, which we shall call the corresponding 'posterior distribution' of p. Under certain conditions on the experimenter's model, which express the idea that the experiments are identical and independent, one can prove that, if the state of Nature is actually in the set $B(p)$, then, *as the number of experiments increases without limit, the sequence of posterior distributions will converge to a distribution that assigns probability one to the set* $B(p)$. Savage calls this 'the approach to certainty through experience.' (For a formal treatment, and references to some relevant literature, see Savage, 1954, 1972, Section 3.6.)

The Simon Critique

As Herbert Simon emphasized in his work, the cognitive activities required by the Savage paradigm (and its related precursors) are far beyond the capabilities of human decision-makers, or even modern human/computer systems, except in the simplest decision problems. This led Simon and his colleagues (especially at Carnegie-Mellon University) to investigate models of human decision-making that are more realistic from the point of view of cognitive demands, and yet do not entirely abandon the notion of rationality. This research also had an impact on the emerging field of artificial intelligence (see Simon, 1972, 1981, and the references cited there).

Savage himself was aware of the problem of bounded rationality, but he nevertheless felt that his model was a useful one for thinking about rational decision-making (Savage, 1954; pp. 16, 17).

Costly Rationality and the Extended Savage Paradigm

As just sketched in the previous section, the Savage paradigm does not appear to take account explicitly of the costs of decision-making. However, nothing prevents the DM from incorporating into the description of the consequences of an act the costs – in terms of resources used – of implementing the corresponding actions. The costly activities involved in decision-making include:

1. observation and experimentation;
2. information processing (i.e., computation);
3. memory; and
4. communication.

The last category may be important when the decision-making process is undertaken by a team of individuals.

If the resources used by these decision-making activities are limited, then those limits may impose binding constraints on the activities themselves, constraints that must be taken into account in the DM's optimization problem. If the constraints are on the *rate of resource use per unit time*, then more extensive decision-making activities may cause *delays* in the implementation of the eventual decisions. To the extent that a delay lowers the effectiveness of a decision (e.g., by making it more obsolete), one may think of delay as an 'indirect cost.' Extending the Savage paradigm to incorporate the costs of decision-making may in some cases be natural, and in other cases problematic. Here the first class of cases is called 'costly rationality.'

The notion that observation is costly was implicit in the Neyman–Pearson theory of hypothesis testing, and was made explicit by Abraham Wald in his pioneering studies of sequential statistical procedures (see Wald, 1950, for an influential codification of his general approach). The cost of observation also figures in more classical (nonsequential) statistical problems such as the design of sample surveys and agricultural experiments. Given some model of the costs of observation, the DM chooses the kind and amount of observation, optimally balancing the expected benefits of additional observations against their costs. Such decision problems fit naturally into the Savage paradigm, although taking account of these costs typically complicates the analysis. For example, in the case of clinical trials and similar problems, the calculation of optimal policies quickly becomes computationally intractable for many problems of realistic size.

Even after the information has been collected, it still must be further processed to produce the required decisions. This information-processing task may be quite demanding. Examples include (1) computing a weekly payroll, (2) scheduling many jobs on many machines, (3) managing multi-product inventories at many locations, and (4) project selection and capital budgeting in a large firm. Such tasks are typically too complex to be handled by a single person, even with the aid of modern computers. In such circumstances the required processing of the information is *decentralized* among many persons in the organization. The theoretical study of decentralized decision-making in an organization whose members have identical goals was introduced by J. Marschak in the *theory of teams* (Marschak and Radner, 1972).

Computer science has provided a number of useful models of information processing by both computers and humans, and the decentralization of information processing in human organizations finds its counterpart in the theories of parallel and distributed processing in computer systems. T. A. Marschak and C. B. McGuire (1971) were probably the first to suggest the use of a particular model of a computer (the finite automaton) to represent the limited information-processing capabilities of humans in economic organizations. S. Reiter and K. R. Mount (2002) were early contributors to this line of research, and went further in analyzing economic organizations as networks of computers. (For more recent developments, see Radner, 1992, 2000; Van Zandt, 1998, and the references cited there.) One conclusion from this literature is the *Iron Law of Delay* for networks of processors of bounded individual capacity. This law can be paraphrased in the following way: "As the size of the information-processing task increases, the minimum delay must also increase unboundedly, even for efficient networks and even if the number of available processors is unlimited" (Radner, 1992, and the references cited there).

Memory storage and communication among humans and computers are also resource-using activities, and cause further delays in decision-making. Both the storage and transmission of information and the results of information processing seem to be relatively 'cheap' compared to observation and processing, at least if we consider computer-supported

activities. The proliferation of large databanks, and the flood of junk mail, telephone calls, and e-mail, lend support to this impression. It appears that today it is much cheaper, in some sense, to send, receive, and store memos and papers than it is to process them. (For game-theoretic models of players with limited memory, see Rubinstein, 1998. For models of costly communication in organizations, and some implications for organizational structure, see Marschak and Reichelstein, 1998.)

Bounded Rationality

Many real decision problems present difficulties that prevent the DM from using the Savage paradigm. Among these difficulties are:

1. inconsistency;
2. ambiguity;
3. vagueness;
4. unawareness; and
5. failure of logical omniscience.

As will be seen, these difficulties are somewhat related and overlapping. In particular, it is difficult to distinguish in practice between ambiguity and vagueness.

Regarding inconsistency, Savage (1954, p. 570) wrote:

> According to the personalistic view, the role of the mathematical theory of probability is to enable the person using it to detect inconsistencies in his own real or envisaged behavior. It is also understood that, having detected an inconsistency, he will remove it. An inconsistency is typically removable in many different ways, and the theory gives no guidance for choosing.

Some inconsistencies have been observed so frequently, and have been so 'appealing' – such as the so-called 'Allais paradox' and 'Ellsberg paradox' – that they have been used to criticize the Savage axioms and to form a basis for a somewhat different sets of axioms (*see* Measurement Theory: Conjoint). In other cases, it has been argued that inconsistent preferences arise because the DM is forced to articulate preferences about which he is not 'sure.' (This explanation is related to vagueness, discussed in a moment.) In particular, this unsureness may be related to uncertainty about what are the states of the world, a circumstance that can lead to a preference for flexibility (also discussed in a moment). Finally, it has been observed in experiments that inconsistencies are more frequent the closer the alternatives are in terms of preference. This observation led J. Marschak and others to elaborate models of 'stochastic choice' (Mcfadden, 1999); (*see* Decision and Choice: Random Utility Models of Choice and Response Time).

Allusion has already been made to the DM's possible vagueness about preferences. However, the DM could also be vague about any aspect of his model of the decision problem, and is likely to be so if the problem is at all complex. Vagueness can be about the *interpretation* of a feature of the model, about its *scope*, or both.

The problem of vagueness of probability judgments is related to deeper issues about the meaning of probability itself, and in particular to the debate about objective versus subjective interpretations of probability. Strictly speaking, the Savage paradigm is based on a subjective (or personal) view of probability, although there are extensions that admit both interpretations in the same model. Savage recognized the problem, and proposed a solution he called *minimax regret*. This topic will be discussed in the section Minimax Regret and Related Methods.

At a moment of time, the DM may be unaware of some aspect of the problem; for example, the DM may be unaware of some future contingencies that could arise, or of some actions that are available to the DM. This phenomenon is particularly interesting if the DM is aware of the possibility that he or she may be unaware of something. For example, if the DM anticipates that in the future he or she will become aware of new acts of which he or she is currently unaware, then the DM may prefer present actions that allow for 'flexibility' of choice in the future. This idea was formalized by T. C. Koopmans, D. Kreps, and others (Kreps, 1992). For other theoretical treatments of unforeseen contingencies, see Dekel et al. (1998).

As a consequence of the preceding considerations, decision theorists recognize that it is impossible for a DM to construct a complete model of his or her 'grand decision problem,' that is, for the DM's whole life! A common research strategy is to suppose that the DM can break up the grand decision problem into subproblems that can be solved independently without (much) loss of utility. Savage called this the device of constructing 'small worlds,' but showed that the conditions for this to be done without loss are unrealistically stringent (Savage, 1954; pp. 82–91).

Finally, I come to what is perhaps the most difficult aspect of truly bounded rationality. Up to this point it has been assumed– if only implicitly – that the DM has no difficulty performing mathematical calculations or other logical operations. In particular, having formulated a decision model, the DM will be able to infer what it implies for his or her optimal strategy. As has already been pointed out, this assumption is absurd, even for small-world models, except for 'Mickey Mouse' problems that are constructed for textbooks and academic articles. The crux of the matter is that in any even semirealistic decision problem, *the DM does not know all of the relevant logical implications of what he or she knows*. This phenomenon is sometimes called *the failure of logical omniscience*. Examples of the failure of logical omniscience include the following:

1. A DM who knows the axioms of arithmetic is uncertain about whether they imply that 'the 123rd digit in the decimal expansion of pi is 3,' unless he has a long time to do the calculation and/or has a powerful computer with the appropriate software.
2. Twenty years ago, a DM who knew the axioms of arithmetic was still uncertain about whether they imply Fermat's Last Theorem.

The following examples are closer to practical life, and possibly more intimidating:

1. Given all that a DM knows about the old and new drugs for treating a particular disease, what is the optimal policy for conducting clinical trials on the new ones?

2. Given all that is known, theoretically and empirically, about business organizations in general, and about telecommunications and AT&T in particular, should AT&T reorganize itself internally, and if so, how?

Savage (1954, p. 7fn) commented on this class of problems:

> The assumption that a person's behavior is logical is, of course, far from vacuous. In particular, such a person cannot be uncertain about decidable mathematical propositions. This suggests, at least to me, that the tempting program sketched by Polya of establishing a theory of the probability of mathematical conjectures cannot be fully successful in that it cannot lead to a truly formal theory.

(For further discussion and references, see the 1972 edition of Savage's book.)

In spite of some interesting efforts (see, e.g., Lipman, 1995), it does not appear that there has been significant progress on what it means to be rational in the face of this kind of uncertainty.

Satisficing, Heuristics, and Non-Bayesian Learning

In view of the difficulties posed by the various manifestations of 'truly bounded rationality,' a number of authors have proposed and studied behavior that departs more or less radically from the Savage paradigm. These will be discussed under three headings: satisficing, heuristics, and non-Bayesian learning.

The term 'satisficing' refers to behavior in which the DM searches for an act that yields a 'satisfactory,' as distinct from an optimal, level of expected utility. The target, or satisfactory, level of expected utility is usually called the DM's *aspiration level*. In the simplest model, the aspiration level is 'exogenous,' that is, a given parameter of the model. More ambitious models describe some process whereby the aspiration level is determined within the model, and may change with experience (Simon, 1972; Radner, 1975). Such aspiration levels are called 'endogenous.' In some problems even optimal behavior bears a resemblance to satisficing. One example is the 'secretary problem' (Radner, 2000).

The term 'heuristics' refers generally to behavior that follows certain rules that appear to produce 'good' or 'satisfactory' results most of the time in some class of problems (Simon, 1972; *Heuristics for Decision and Choice*). For example, the calculation of an optimal schedule for assigning jobs to machines is typically intractable if the numbers of jobs and machines are even moderately large. Nevertheless, human schedulers routinely construct 'satisfactory' schedules with such numbers, using various rules-of-thumb that have been developed with experience. Heuristics are central to many artificial intelligence applications. Satisficing plays an important role in many heuristic methods, and also in the processes of their modification.

The discussion of heuristics leads naturally to the consideration of *non-Bayesian learning* (NBL) (Cf. the discussion of Bayesian learning earlier in the article). Many standard statistical methods use NBL. For example, the use of the sample mean to estimate a population mean is typically inconsistent with the Savage paradigm (although in some cases the latter can be shown to be a limit of Bayesian estimates as some parameter of the problem goes to infinity). Most psychological theories of learning postulate some form of NBL. A central question in the theory of NBL is: under what conditions, if any, does a particular NBL procedure converge asymptotically to a procedure that is Savage-paradigm-optimal as the DM's experience increases? (Rustichini, 1999).

Attempts to Define Bounded Rationality

This section briefly examines a few procedures that have been considered by some to provide a 'rational' way to deal with some of the cognitive limits faced by decision-makers, especially in the context of uncertainty.

Minimax Regret and Related Methods

Several approaches are based on estimates of how much is lost by not using an 'optimal' strategy. Using the terminology of the Savage paradigm, let $u(f, s)$ be the utility of an act f in a state s, and define the corresponding regret $r(f, s)$ to be the difference between the maximum utility possible in that state minus the utility of f in that state.

The first strategy we examine is a response to the situation in which the DM is vague about the appropriate prior distribution of the state of Nature – or *prior*, for short. Let $R(f)$ denote the maximum of $r(f, s)$ over all states of Nature, let R^* be the minimum of $R(f)$ over all acts, and let f^* be an act that attains R^*. (Assume that the relevant maxima and minima exist.) The *minimax regret rule* prescribes that the DM should choose an f^*, *provided that* R^* *is not too large*.

The minimax rule is typically expanded to include randomization: (1) the set of states is replaced by the set of probability distributions on the set of states, that is, by the set of possible priors; and (2) the set of acts is replaced by the set of probability distributions on the set of acts. Note that this expansion transforms the decision problem into a zero-sum game against 'Nature.' Savage (1954, pp. 169–171) also argued against using negative utility instead of regret (Radner and Marschak, 1954).

Savage ascribed the minimax rule to Abraham Wald (1950), although Wald did not motivate it in a formal way. Indeed, Savage himself stated: "A categorical defense of the minimax rule seems definitely out of the question… On the other hand, there are practical circumstances in which one might well be willing to accept the rule… It is hard to state the circumstances precisely, indeed they seem vague almost of necessity" (Savage, 1954; Section 9.7).

(Savage used the term 'loss' instead of 'regret.' He also proposed the minimax rule for statisticians, but for a different reason, which is beyond the scope of this article to discuss.)

More recently, several authors have proposed sets of axioms to rationalize the minimax regret rule and variations of it. In some cases, authors use the term 'ambiguity' instead of 'vagueness,' although the distinction is sometimes difficult to discern (Stoye, 2011, 2012 contains recent contributions and previous references). For recent theories of updating such

rules in the light of new information, see Hanany and Klibanoff (2009). In particular, some authors have proposed a mixed model, following ideas of Frank Knight (Knight, 1921), distinguishing 'risk' from 'uncertainty,' with the former objectively quantifiable, and the latter subjective or even not quantifiable. DMs are sometimes modeled as having the analog of two probability distributions and two utility functions, one pair of scales appropriate for risk and the other for uncertainty (ambiguity). However, it can be argued that, in the presence of vagueness about beliefs, it is paradoxical to assume that the DM can articulate two separate pairs of scales as above.

This would leave minimax regret as the most promising candidate for rational behavior in the presence of vagueness of beliefs. Related ideas are strategies for which the DM can compute an upper bound on the regret that is perceived, in some sense, as not too large.

Asymptotic Rationality

Procedures that fall outside of the Savage paradigm are often justified as converging to optimality with the accumulation of experience. For example, NBL statistical estimation procedures are valued if they are *consistent*, meaning roughly that the estimates of a parameter converge to the 'true value' of the parameter as the sample size increases without limit. Under the conditions that guarantee the approach to certainty of Bayesian methods (discussed earlier), this implies that the NBL estimator is asymptotically optimal in the Savage sense. Another example is asymptotically optimal model revision in the case of vagueness about specification of the model of the decision problem (Radner, 2009; Rustichini, 1999). Thus asymptotic rationality is a promising candidate for bounded rationality.

Survival and Evolution

Survival in an individual or evolutionary sense is sometimes taken to be a sign of – or definition of – rationality. For an individual, survival is a matter of preference. A long, miserable life is not necessarily preferable to a short, happy one. Discussion of evolution as a criterion of rationality would take us beyond the scope of this article, which has been focused individual decision problems (see, however, Dutta and Radner, 1999; Smith, 2008).

Conclusions

This incomplete survey has listed a number of ways that limited cognitive abilities prevent the full applicability of the Savage paradigm of rationality in individual and team decision problems under uncertainty. These limitations gave rise to the study of the stimulating but vaguely defined concept of bounded rationality. Some of these limitations could be dealt with under the rubric of costly rationality, without departing from the Savage paradigm itself. Others forced us to go beyond the Savage paradigm, but thus far no clear-cut concept of rationality has emerged from the study of responses to these limitations, although a few look promising. In particular, no persuasive rational response to the failure of logical omniscience seems to have been discovered. Hence the concept of bounded rationality still seems to be in need of a definition.

Bibliographic Notes and References

Many important works on bounded rationality have been omitted from the bibliography because of space limitations. The references cited in the body of the article have historical interest, provide an overview of a topic discussed, and/or provide a key to other literature. The following provide additional references and information on the application of notions of bounded rationality in economics and management: Arrow (1974); Binmore (2009); Gintis (2009); Hansen and Sargent (2007); Radner (2000); Shapira (1997); Smith (2008); and Van Zandt (1999).

Acknowledgments

Some of the material in this article is a condensation of Radner (2000). I thank the Oxford University Press for permission to use this material here.

Decision and Choice: Economic Psychology

Stephen EG Lea, University of Exeter, Exeter, UK

Abstract

Economic psychology is the interdisciplinary study of the economic behaviors of individuals, and of the impact of the state and nature of the economy, and individuals' positions within it, on individual behavior and mental life. Economic psychologists have focused their attention on questions such as the psychology of saving, debt, and investment; the psychology of money and taxation, both in terms of individuals' compliance with or avoidance of tax, and the psychological impact of tax systems; and the psychological impacts of major economic changes such as the recent financial crisis, the recognition of the ecological unsustainability of some current economic models.

Introduction

Economic psychology is best defined by what economic psychologists do. Typically, they are interdisciplinary social scientists who recognize that the economy is an important field of human behavior and that human beings are important agents in the economy. Those may seem obvious, even banal, propositions. However, a consideration of the most influential theories and schools in psychology would show that they have often ignored economic behavior, in favor of looking at intimate relationships, emotional development, or very general processes. Conversely, it is now almost a cliché that for most of the twentieth century economic theory was dominated by mathematical approaches that abstracted from the living human economic agent, relying on assumptions that people would, to a good enough approximation, do whatever was economically best for them.

Both those approaches have exploded spectacularly in the final decades of the twentieth century and the first decade of the twenty-first century. This has come about partly for academic reasons: social scientists from both economics and psychology have started to take a serious interest in each other's disciplines. More important, however, has been the occurrence or projected occurrence of a series of crises in the economic world: The shift of economic power from North America and Europe toward Asia; the growing realization that the current model of economic policy is unsustainable ecologically; the demographic changes that mean that many, perhaps most, in the traditional developed world cannot rely on having an adequate income for what has been thought of as normal retirement; and, most recently, the prolonged and widespread recession triggered by excessive reliance on credit by governments and financial institutions' promotion of unsustainable loans to individuals. All these are economic changes that have been widely perceived to have profound causes within individual behavior, and profound consequences of individuals' lives, including their mental lives. These developments therefore make it painfully obvious that the economy matters to individuals and individuals matter to the economy.

To put this more formally, economic psychology recognizes that (1) the economy powerfully influences individuals' lives, at the psychological level of feelings, thoughts, and behavior, (2) individuals' feelings, thoughts, and behavior are what make up economic life, and (3) there are many problems, both academic and practical, to which economics and psychology can both contribute despite their very different approaches and explanatory styles.

Relation of Economic Psychology to Other Research Areas

Economic psychology is not a branch of psychology, but the interdisciplinary study of the interface – or, as it tended to be for much of the twentieth century, the gap – between economics and psychology. One of the most powerful and successful ways of looking at that interface has been through the study of economic decisions, particularly in the area of risky choice, limitations on rationality (see Decision and Choice: Costly and Bounded Rationality) and intertemporal choice. So an entry on economic psychology is fittingly placed in this volume, alongside discussions of numerous other aspects of decision theory. However, it is equally strongly linked to articles in this encyclopedia devoted to economics, to developmental, social, personality, and motivational psychology, to organizational and management studies (for example, Customer Satisfaction or Marketing Strategies), and so on.

Even when economics and psychology had the least interest in each other during the mid-twentieth century, a few very distinguished researchers moved freely between the two disciplines, and have been recognized and respected in both disciplines. However, many of them would be more likely to identify themselves as decision theorists than as economic psychologists: examples include Herbert Simon, Amos Tversky (see Tversky, Amos (1937–96)), Richard Thaler, and George Loewenstein. It is true in general that many more people practice economic psychology than call themselves economic psychologists. Very similar approaches are taken not only in decision science but also under other interdisciplinary names, such as behavioral economics, consumer science, or socioeconomics, and within particular branches of both psychology and economics (see Behavioral Economics; Experimental Economics). Individual researchers may designate themselves in different ways within this spectrum, but they mix freely with others who would describe themselves differently, and the

 http://dx.doi.org/10.1016/B978-0-08-097086-8.43029-1

institutions of research such as learned societies and their conferences and journals draw on all of them. Because so many of these areas of research are represented elsewhere in this encyclopedia, this article will focus on the work of those who have explicitly thought of themselves as economic psychologists.

Of these various terms describing interdisciplinary research between psychology and economics, 'economic psychology' is probably the oldest: it was used, probably for the first time, in the title of a book by the influential French social psychologist Gabriel Tarde (1902). However, the modern development of economic psychology started from the work of the Hungarian-American Gestalt psychologist George Katona in the period immediately after World War II. Katona's work is summarized in his book, *Psychological Economics* (Katona, 1975). Recent surveys of current research include Altman (2006) and Lewis (2008); it is significant that both placed research by economic psychologists side by side with work by decision theorists and experimental and behavioral economists.

Although there are certainly no barriers between those who describe themselves in these different ways, there are certainly different nuances associated with the different descriptions. To locate the term more accurately, therefore, it is worth considering what differences exist between people describing themselves as economic psychologists and their colleagues who would describe themselves in other ways. It should be emphasized, however, that these are trends only, and many exceptions could be found.

Unsurprisingly, compared with those who call themselves behavioral economists, those who call themselves economic psychologists are more likely to have had their initial training in psychology, rather than economics, and to have worked in psychological institutes of one sort of another, rather than in economics departments. This is not just a matter of personal history; they are more likely than behavioral economists to make use of general psychological theories and methodologies. At the theoretical level, they are particularly likely to use cognitive social psychological theories such as Fishbein and Ajzen's theories of reasoned action and planned behavior, or more recent ideas such as social identity or self-regulation theory. They may use other theories as well: evolutionary theories have been particularly popular in recent decades, for example, but these are equally popular among interdisciplinary researchers of other orientations. Methodologically, although there has been a huge increase in the use of experimental studies of social dilemmas such as the ultimatum game and trust games, economic psychologists still often use questionnaire surveys or depth interviews followed by qualitative analysis. Furthermore, if they use experiments, these may well involve asking participants to imagine themselves into a scenario, and may well not implement incentive compatibility, rather than the very bare but always incentive-compatible approaches favored by experimental economists.

Compared with those who call themselves decision theorists, economic psychologists are less likely to be concerned with exact or mathematical models of people's choices, and in particular, they are less likely to be concerned with the minutiae of rationality or optimality models, let alone with submitting such models to empirical test. They are typically more concerned with descriptive analyses of actual economic choices, often choices that are part of everyday economic life, than with mathematical analyses of more abstract choices in experimental or other artificial situations. They are also likely to call on a wider range of psychological constructs: decision theory largely draws on and influence concepts within cognitive psychology, and indeed many of its leading exponents would be happy describing themselves as cognitive scientists. Economic psychology, however, is concerned also with the economic role of emotions; recent research has been looking at the economic sources and defects of anger, guilt and shame, and pride and self-esteem.

Quantitatively speaking (that is, in terms of their contributions to household income or expenditure, and the hours people spend engaged in them), the most important kinds of economic behavior are working and buying. These are so significant that they have their own branches of both psychology and (to some extent, at least) economics. Within psychology, the study of work behavior falls within the field variously known as occupational psychology, industrial and organizational psychology, or work psychology, while the study of buying behavior falls within consumer psychology. Within economics, the study of work behavior falls within labor economics. The study of buying behavior offers an interesting example of the problems of twentieth-century economics. In principle, it should fall within microeconomics, and specifically within demand economics. However, for most of the twentieth century, this field was so focused on abstract mathematical theory, and so divorced from the study of actual purchasing behavior, as to be of no use to anyone interested in what people actually buy and why. Empirical economic data on buying behavior therefore have to be sought elsewhere, within econometrics, applied especially to agricultural economics, and various areas of management studies particularly those devoted to retail management.

Logically, all these fields of study are subfields of economic psychology as defined here. It is certainly true that experts in all these fields can be found within the research institutions of economic psychology, and that people calling themselves economic psychologists have carried out much research on both work (e.g., Nyhus and Pons, 2005) and buying (e.g., Dittmar, 2008). However, economic psychology as a discipline would certainly not be so arrogant as to claim these much larger groups of colleagues as its subordinates (cf. Lea, 1992). Furthermore, there are some typical differences in approach to the subject matter of work or buying between people calling themselves economic psychologists and people calling themselves, say, consumer psychologists or labor economists. First, an economic psychologist is more likely to be interested in work or buying as examples of economic behavior in general, and to ask how they illuminate general questions about the relation between the individual and the economy. Second, these more specific fields do typically lie firmly within either economics or psychology: consumer psychologists are clearly psychologists and have little to do with microeconomists or econometricians, and labor economists are clearly economists and have little to do with occupational psychologists. An economic psychologist looking at work or buying, however, is almost inevitably going to do so from an interdisciplinary perspective. Of course, there are some exceptions to these broad

trends: for example, compulsive buying, logically a topic within consumer psychology, has disproportionately been studied by people who would be more likely to describe themselves as economic psychologists, while unemployment, logically a topic within occupational psychology, has also been more of a concern within economic psychology.

Finally, compared with all these other kinds of work that draw on both economics and psychology, economic psychologists have been more likely to be interested in the two-way interaction between individuals and the economy. It is common ground among economic psychology, behavioral economics, and decision theory that the economic decisions of individuals are interesting, that they are at least in part predictable, and that they have serious consequences for the behavior of the economy as a whole. However, it is only within economic psychology that one finds much study of the converse direction of causation – a consideration of the impact the economy as a whole has on the individual. As we turn to a consideration of what, specifically, economic psychologists do, we will do so in two parallel sections: one concerned with the economic behaviors of individuals, the other with the economy as an independent variable acting on individuals' psychology.

Economic Behaviors of Individuals

Economic behaviors include, for example, work, buying, saving, borrowing, giving, and gambling. Several of these have been subjects of intense research within psychology. We have already seen that both work and buying have whole areas of both psychology and economics devoted to them. It is no accident, therefore, that many economic psychologists have concentrated on economic behaviors such as saving, borrowing, giving, and paying (or avoiding) tax, which are left aside by the established subdisciplines.

The study of saving, debt, and investment has been one of the most popular research areas for economic psychologists, for a number of reasons. First, it is macroeconomically important. Katona's consumer surveys focused on how much of their incomes consumers intended to spend rather than save, since quite small changes in this 'propensity to consume' can tilt a modern economy into recession or inflation. Second, the problem of optimal intertemporal choice is theoretically interesting and difficult: economists have often had to appeal to (usually speculative) psychological principles to reconcile their theories with some obvious macroeconomic facts. Third, it is important in the lives of individuals: making adequate provision for future life changes such as children's education or one's own retirement is a difficult and complex matter, while getting involved in serious debt or bankruptcy can be a personal disaster. Finally, the problems have proved tractable to psychological investigation. Wärneryd (1999) has summarized extensive research that has given us a thorough understanding of the psychological processes leading some people to save more than others. Recently, the study of intertemporal choice has become a key field within behavioral economics, from the point of view of investigating individuals' choices in experimental situations and that of seeking ways of encouraging people to make better choices in real-life situations (see Thaler and Sunstein, 2008). However, it has also spread into new areas of psychology, particularly with the involvement of techniques for exploring the areas and processes of those involved in particular choices, using techniques such as electroencephalography, functional magnetic resonance imaging, and most recently pharmacological intervention. These approaches, often collectively referred to as neuroeconomics (see Glimcher, 2010), have been applied to other kinds of choices (for example, those in social dilemmas) as well as intertemporal choice.

The study of debt does not have such a long history in economic psychology as the study of saving, but in recent years it has become more and more prominent. Like the decision to save, the decision to borrow is an intertemporal choice, but from the research that has been done on such fields as serious household debt, bankruptcy, credit card use, and purchase through installment credit (hire purchase), it has become clear that the psychological processes involved are far from being mirror images of each other. In many countries a particular sphere of research has been the study of debt and borrowing by university students, as governments have sought to transfer more of the financing of higher education from taxation to loans. The investigation of the psychology of debt will obviously be given new impetus by the role that unsustainable personal borrowing played in the bank crashes of 2007 onwards, and the higher levels and pervasiveness of debt that are likely to be seen in the ensuing time of economic hardship in many Western economies.

If debt is logically the opposite of saving, investment is its logical consequence: anyone who uses a financial institution for the purposes of saving is also making an investment. The psychology of investment is not well developed. There has been some research on the influence of investor psychology on movements within stock markets; Wärneryd (2001) provides a summary. However, the most thorough research has been on something that is, in terms of the financial markets as a whole, a niche area, namely, ethical investment. This has been of concern partly for practical or political reasons, because it is seen as something that should be encouraged, and partly for theoretical reasons, since it bears on the apparently vexed question of altruistic behavior. This is more fully considered within the study of the psychology of giving.

The psychology of giving has attracted a great deal of popular attention. It is theoretically interesting because of its relation to the whole question of altruistic behavior, which is at least superficially paradoxical within both economic and evolutionary theories. The paradox is at least partly resolved by noting that gifts illustrate in a vivid way a general principle: every gift is both an economic and a social transaction. Within any society there are well-understood, although usually unstated, social rules about what may be given to whom and on what occasions. For example, despite the longstanding protests by economists that money is actually the most efficient kind of gift, so that the practice of choosing objects to give to someone else results in a substantial deadweight loss, money is not a socially acceptable gift in all contexts. For example, in the United Kingdom, young adults typically do not find the idea of giving money to their mothers as a birthday present acceptable. Interestingly, the objections are

felt more strongly by the potential donor than by the potential recipient.

Almost all economic behaviors involve money in some way. A central problem for economic psychologists has therefore been the psychology of money itself. The problem is more acute because modern 'fiducial' money is inherently a psychological creation: it is valuable only because we all believe it is. Economic psychologists have investigated what makes 'good' money, from the kinds of coins that look and feel valuable to people, to the kinds of electronic payment that do not leave people feeling they are out of control of their spending. Transitions to new kinds of money have also been investigated; this concerns not only the Euro but also the rebasing of currencies in response to serious inflation, which on a world scale happens quite frequently. Economic psychologists have also investigated some of the unexpected behaviors people show toward money, for it seems to be a general rule that money attracts a certain amount of behavior that is disproportionate to its actual economic usefulness. Lea and Webley (2006) have reviewed much of the recent literature on the psychology of money, in the process of arguing that some aspects of human behavior toward money cannot be explained by its instrumental (or, as they put it, 'tool-like') properties, but instead require us to see money as a kind of drug, which gives some of the same gratification as biologically relevant stimuli without fulfilling any real biological need.

An important aspect of the psychology of money is the psychology of money management. What makes some people better than others at the task that faces nearly all of us, living in a world where the supply of desirable goods greatly exceeds the income available to buy them? In multiperson households, how are resources shared, and who determines the economic choices that are made on behalf of everyone? In recent years this aspect of family economics has been extended from traditional nuclear families to consider a wider range of household arrangements, such as the blended families that follow divorce and remarriage.

Cutting across all these fields, but commanding ever-increasing attention, are environmental and other ethical concerns. Individual economic behaviors are involved in concerns about the sustainability of the current Western economic model in two ways. On the one hand, there are many individuals who want to adjust their personal economic behavior so as to reduce their impact on planetary ecology (and perhaps to influence other individuals, and the political process, to do the same). They may do this in a variety of ways, all of which have been studied by economic psychologists. Studies of ethical investment have already been mentioned, but there are also investigations of ethical (usually environmentally oriented) workplace behavior, consumption, and giving. It has been the general argument of this section of the article that the economic behaviors of individuals are relevant to the behavior of the economy as a whole. Indeed, from the point of view of the traditional doctrine of consumer sovereignty, they are not just relevant but determinative: as a Ford Motor Company advertisement once put it, "Everything we do is driven by you." For the most part the assumption is that, however economically important individuals' choices are, we neither know nor care about their macroeconomic impact. When people make ethical economic choices, however, they are typically deliberately trying to bring about a particular economic effect.

The Impact of the Economy on Individuals' Psychology

At any moment, within any given economy, different individuals occupy different positions, from millionaire to beggar; even the most stable economy undergoes unpredictable macroeconomic changes, from growth to recession, and sometimes many economies do so in parallel; some economies undergo massive transformations, for example, the 1990s transition from state socialism to market capitalism in Eastern and Central Europe and the former Soviet Union, and the rather different development of a capitalist model within the People's Republic of China; within economies, individual industries and industrial sectors wax and wane; and across the globe there are huge variations between countries in people's average earnings, spending power, and standards of living. These many different dimensions of economic variation must have profound psychological consequences, yet the economy is traditionally ignored as an independent variable within psychology. Economic psychologists have sought to repair this omission.

A popular methodology has been to look at how children learn to function within the particular economy they are born into. This is known as the study of 'economic socialization' (Furnham, 2008). Many earlier studies took a cognitive stance, investigating how children's understanding of economic concepts improves with age. More recent work has tended to look at children's actual economic behavior, and have led us to realize that, as well as interacting directly with the adult economy, children have at least two other kinds of economic life. They are potent influences on the economic behavior of their entire households, both through their unarguable needs and through their ability to influence their parents' consumer and occupational choices. In consequence, children are the target of major advertising and marketing campaigns, and the legitimacy and effectiveness of these has been keenly debated. Second, however, children live in an entire economic world of their own, involving exchange transactions that are at best tangentially related to the adult economy. They may show much more sophisticated economic understanding in these transactions than they reveal in the traditional studies of the development of economic understanding.

Another widespread approach to considering the economy as an independent variable has been comparative study, either cross-sectional or (more rarely) longitudinal. Cross-sectional studies include a series of impressive collaborative cross-national investigations, for example, of tax evasion and of attitudes to the Euro when it was introduced (Pepermans et al., 1998). The many institutional differences between nations mean that such comparisons can give a good insight into the effective economic variables producing differences between people.

Longitudinal studies within single economies or groups of economies are also increasingly important, aided by the increasing availability of data from panel studies, and the increasing number of them that include at least some questions

suggested by economic psychologists. Such studies can throw light on the impact on individual psychology of macroeconomic changes, such as inflation, economic growth, or recession.

Where such formal comparisons are not feasible, 'impact studies' have been popular: people in a particular economic position are interviewed or given psychometric tests to try to understand how they differ from more typical populations. Such studies have, for example, looked at the impact of the tourist economy on its host populations, at the kinds of coping behavior elicited by living in poverty within a wealthy society (Anand and Lea, 2011, introduce a journal special issue devoted to this question), and the impact of unemployment and retirement.

In many such impact studies, the key dependent variable has been individual happiness or life satisfaction. While there are still skeptics around, the measurement of happiness has gone from being a pursuit so 'soft' that no serious social scientist, and certainly no economist, should contemplate it, to being an accepted tool by which governments' policies and performance should be judged. Interest in happiness and its antecedents of course runs much more widely than economic psychology, but it is perhaps the clearest possible example of the proposition, central to economic psychology, that the economic system and the individual's position within it are crucial independent variables in individual psychology.

The impact of the economy on individuals, and the impact of individuals on the economy, of course go together; there is a cycle of causality between the two, which means that the impact of changes will never be entirely predictable from studies that isolate one process or the other. A good example of this occurs in the psychology of taxation, reviewed by Kirchler (2007). On the one hand, economic psychologists have looked at individual behaviors, particularly tax evasion and avoidance; on the other hand, the tax regime in an economy induces changes in such behaviors – its perceived fairness, for example (or the extent to which individuals can plausibly represent it to themselves as unfair), may have a marked effect on tax compliance.

In the first decade of the twenty-first century, the most important economic event within the so-called developed world has been the financial crisis that started in 2007. Research on its psychological impacts has been started in many institutions, but at the time of writing little had found its way to formal publication. It is clear that, despite the fact that behavioral economists are close to several Western governments, many governments' handling of the crisis has been far from ideal from a psychological perspective; not only have steps that seem obvious from the known psychology of previous recessions not been taken but also precisely opposite measures have been put in place in some cases.

From a longer perspective, however, it may turn out that the crisis in the 'Western' economies is not as important in world economic history as the rise of some 'non-Western' countries. It is widely recognized that the so-called BRIC countries (Brazil, Russia, India, and China) have the potential to eclipse the current leading world economies by the mid-twenty-first century; commentators are busily coining terms for other groups, such as MIKT (Malaysia, Indonesia, Korea, Turkey) or CIVETS (Colombia, Indonesia, Vietnam, Egypt, Turkey, and South Africa), that are showing signs of coming to prominence in the wake of the BRICs. There are increasing signs that the long-term economic underperformance of the whole continent of Africa may be ending. A key question is what psychological impact may follow from the explosive growth that such economies are undergoing or may soon undergo. That question is so far unanswered; but every one of the BRIC countries has active groups of economic psychology researchers within them, and there are at least individuals trying to establish economic psychology as a field of research within all the MIKT and CIVETS countries.

Economic Psychology in a New Economic Era

Throughout the twentieth century, economic psychology struggled to establish itself as an interdisciplinary study, in the face of an academic discipline of economics that was dominated by a single theoretical idea, rational self-interest. The focus of twentieth-century economics was theoretical, and much of its theory consisted of working out what a rationally self-interested individual would do in a given situation. Economic psychologists, although not all psychologists by initial training, shared with the discipline of psychology an interest in what people actually do, and a corresponding indifference to any single theory. Furthermore, the empirical bias of psychologists led them, as soon as they started to look at economic behavior, to question the economic assumption of rational self-interest. This means that a great deal of research in economic psychology consisted of investigations by psychologists of the empirical accuracy of theories developed by economists.

In the past two decades, that intellectual environment has changed radically, for two reasons. First, recognizing the various difficulties associated with a frontal assault on rationality assumptions, most economic psychologists ceased testing rationality assumptions directly, but rather set about trying to build empirically valid models of the causation and consequences of economic behaviors. Popular causal variables include personality differences, attitudes, socialization experiences, and psychological disorders. All these variables can potentially cause different people, exposed to apparently identical economic situations, to react in different ways. They thus allow psychologists to account for some of the individual variation in behavior that remains when the obvious economic variables have been taken into account. Cumulatively, of course, such studies can still constitute a powerful attack on the economic theory of rational self-interest. There are many ways of acting rationally in any given situation, depending on one's knowledge, abilities, values, and goals. If most of the variation between people's economic behavior actually depends on which rational behavior people choose, and if this has to be predicted from psychological properties of the person, the role of economic psychology has to increase, while the role of rational theory as such has to decrease.

Second, however, the discipline of economics has changed. Behavioral and experimental economics have

become enormously influential. Within economics, it is now accepted by many – although probably not by most – that economic behavior is not completely described by rational choice models; that deviations from rationality are systematic and substantial; that such deviations can be predicted from known processes in cognitive, social, comparative (and perhaps clinical, developmental, and evolutionary) psychology; that they can be studied in laboratory experiments; and that the results will be predictive for the real economy. The implication is that an economics (and hence an economic policy) that does not take account of psychological processes and data is radically incomplete. This view is widespread within academic economics; it is widely given credence within the consumers of economics, that is, governments and their economic advisors. Of course there are still many economists who would want to defend the assumption of rationality, and to argue that some of the psychological predictions about economic behavior are exaggerated or lack generality. Even they recognize that the defense must now be on empirical grounds; and on such grounds, economics and psychology can always meet.

Abstract

Heuristics are approximate strategies for decision making. They do not process all the available information and therefore can yield a reasonable solution fast, even in conditions of incomplete or uncertain information. The same, or similar, heuristics can be used in both preference tasks (e.g., choosing between consumer products) and inference tasks (e.g., which of two cities is larger), but some were traditionally studied in the preference, and some in the inference, context. There is also a tradition of studying heuristics that are used primarily in social contexts.

Introduction

Heuristics are approximate strategies or 'rules of thumb' for decision making and problem solving. They do not process all the available information and therefore can yield a reasonable solution fast, even in conditions of incomplete or uncertain information. Heuristics are most commonly studied in psychology within the domains of judgment and decision making, social cognition, and problem solving, and in the fields of artificial intelligence, operations research, and behavioral biology. This article focuses on heuristics proposed as models of how people make decisions and choices.

Historical Overview

The term *heuristic* is of Greek origin and means 'to find out' or 'discover.' Gestalt psychologists proposed heuristic methods to guide searches for information (Duncker, 1935). The mathematician George Pólya (1945) distinguished heuristics from analytical methods: for instance, heuristics are needed to find a proof, whereas analysis is for checking a proof. Pólya's student Allen Newell, together with Herbert Simon, developed models of heuristics to limit large search spaces with applications in artificial intelligence and cognitive science (see Newell Shaw and Simon, 1958). Mathematical psychologists (Luce, 1956; Tversky, 1972; Dawes, 1979) and others studied models of heuristics for choice, such as lexicographic rules, elimination by aspect, and equal-weight rules. Behavioral biologists studied experimentally the rules of thumb that animals use for choosing food sites, nest sites, or mates (see Hutchinson and Gigerenzer, 2005). Psychologists in the 1970s became interested in demonstrating human reasoning errors that they believed are the consequence of using heuristics (Tversky and Kahneman, 1974). They focused on studying when verbally described heuristics break down and yield deviations from classical norms of rationality (Kahneman et al., 1982). The resulting heuristics and biases program has had immense influence, contributing to the emergence of behavioral economics and behavioral law. An alternative approach focused on the adaptive nature of heuristics and investigated how computationally modeled heuristics can exploit structured information to yield fast and accurate decisions (Gigerenzer et al., 1999). Studies conducted in this tradition showed that when used in the appropriate environment, heuristics can surpass the predictive accuracy of more sophisticated and information-greedy tools, including that of regression models or neural nets (Gigerenzer and Brighton, 2009). Recently, there have been attempts to integrate different views of heuristics. For example, Shah and Oppenheimer (2008) proposed that different heuristics share the same goal of effort reduction by examining fewer attributes (also called aspects, cues, or features), reducing the effort of retrieving attribute values, simplifying the weighting of attributes, integrating less information, and examining fewer options.

Evaluating the Performance of Heuristics

Heuristics, as well as any model of decision processes, can be evaluated according to how well they describe people's choices and how well they correspond to normative criteria of accuracy. What normative criteria can be used depends on the nature of the task. In preference tasks, such as choosing between consumer products or monetary gambles, the accuracy of a heuristic can only be determined by assessing how closely its predictions match that of some gold standard for rational preferences, such as maximizing expected utility. In inference tasks, such as which soccer team will win or which of two cities is larger, the accuracy of heuristics is judged by their ability to predict real-world outcomes. The same, or similar, heuristics can be used in both preference tasks and inference tasks, but some were traditionally studied in the preference and some in the inference context. There is also a tradition of studying heuristics that are used primarily in social contexts. Success of these heuristics is also judged by criteria such as fairness, coordination, and equality.

Heuristics for Preferences

The typical normative approach to choice in preference tasks involves weighting and combining all of the available attributes of different options, with the weights determined by a process such as multiple regression. Several heuristic

alternatives to this standard approach have been proposed. Simon's (1955) satisficing heuristic searches through options, stops as soon the first option exceeds an aspiration level, and chooses this option. In Selten's (1998) aspiration adaptation theory, the aspiration level can change throughout the decision process. A family of models called lexicographic heuristics search through attributes (Fishburn, 1974). In their simplest form, attributes are inspected one at a time, and the option with the best value on that attribute is selected. In the case of a tie on the most important attribute, the tied options are searched again according to the second most important attribute, and so on until choosing a single option. Perhaps the best-known member of the lexicographic family is the elimination by aspects heuristic (Tversky, 1972). According to this heuristic, decision makers select and establish a cutoff value for the most important attribute. Decision makers eliminate any options that do not satisfy the criterion value on this attribute and continue to choose attributes in this manner until only one option remains. Payne and colleagues (Payne et al., 1993) provided evidence that the performance of these and other lexicographic heuristics can approach that of a weighted-additive rule while minimizing effort. A recent lexicographic rule for choices between gambles is the priority heuristic (Brandstätter et al., 2006).

Heuristics for Inferences

Many heuristics for inference tasks are also part of the lexicographic family of models, searching sequentially through attributes of different options. The take-the-best heuristic infers which of two options has a higher value on a criterion, based on binary attribute values retrieved from memory where attributes are ordered in descending order of their validity. Lexicographic heuristics can also be applied to categorization (or classification), where the task is to assign an object to one of several categories. These heuristics are called fast and frugal trees (Martignon et al., 2003).

Other heuristics only consider one piece of information. The recognition heuristic (Gigerenzer et al., 1999; Goldstein and Gigerenzer, 2002) considers the single cue of recognition: when one option is recognized and the other is not, this heuristic chooses the former and otherwise guesses. The fluency heuristic, formulated for situations where both options are recognized, chooses the option that was recognized faster (Schooler and Hertwig, 2005).

Some heuristics use all available attributes but follow an equal weighting principle (also called tallying, unit- or equal-weights regression), reducing cognitive demand. Equal weights models can even outperform weighted models such as multiple regression in terms of predictive accuracy (Dawes and Corrigan, 1974; Dawes, 1979). Another variant of the equal weighting principle is the 1/N rule, which is a heuristic for the allocation of resources, such as time or money to N alternatives. This heuristic has been shown to work well in investment situations (DeMiguel et al., 2009).

Several heuristics have been proposed for judgments of probabilities or other quantities (Kahneman et al., 1982; Gilovich et al., 2002). The representativeness heuristic (Kahneman and Tversky, 1972) judges the probability that an object A belongs to a particular category B (e.g., that a person described as a feminist is a bank teller) or that an event A is generated by a particular process B (e.g., that the sequence TTHHHH was generated by throwing a fair coin), based on the extent that A is representative of, or similar to, B. The availability heuristic (Tversky and Kahneman, 1973) judges class frequency or event probability based on how easily instances of the class or event can be mentally retrieved or constructed (e.g., plane crashes may seem like a frequent cause of death because it is easy to recall examples). The anchoring-and-adjustment heuristic (Tversky and Kahneman, 1974) judges quantities by starting with a particular value (the anchor) and adjusting from it (e.g., quick estimates of $8 \times 7 \times 6 \times 5 \times 4 \times 3 \times 2 \times 1$ are typically higher than quick estimates of $1 \times 2 \times 3 \times 4 \times 5 \times 6 \times 7 \times 8$, because the result of the first few steps of multiplication is higher in the former case). These heuristics have been criticized as being vague redescriptions of observed choice behavior that are difficult to falsify. Kahneman and Frederick (2002) strengthened the definition of the representativeness heuristic and proposed that it worked by attribute substitution, that is by replacing a computationally complex attribute (e.g., probability) by one that is more readily available (e.g., similarity). This enabled researchers to implement computational versions of the representativeness heuristic and compare them with other models of how people judge probabilities (e.g., Nilsson et al., 2005). The definition of the availability heuristic has also been strengthened by implementing mechanisms consistent with the original formulation (Sedlmeier et al., 1998).

Heuristics for Social Contexts

Heuristics described so far can also be used to solve problems in social contexts. Attributes used in lexicographic heuristics can be social in nature, for instance, whether one's friends chose one or the other option. Social information can be used to find the best attribute order in the take-the-best heuristic (Garcia-Retamero et al., 2009), and groups can profit from relying on members who can use a particularly useful heuristics (e.g., those who recognize only one of two options and therefore can use recognition heuristic; Reimer and Katsikopoulos, 2004). Rules such as tallying and 1/N can be used to make group decisions and determine how to distribute resources within a group (Hastie and Kameda, 2005; Hertwig et al., 2002).

Other heuristics are used primarily in social contexts. Simple rules such as tit-for-tat, tit-for-two-tats, or win-stay-lose-shift (Axelrod, 1984; Nowak and Sigmund, 1993) can help maintain a high level of cooperation in the group and prevent harmful effect of defectors. To choose whom to learn from, animals including humans use rules such as 'copy the majority,' 'copy if rare,' 'copy successful,' 'copy older individuals,' 'copy kin,' and 'copy friends' (Boyd and Richerson, 1985; Laland, 2004). To decide whether to use social learning in the first place, useful rules can be 'when individual learning is costly,' 'when individual information is not relevant' or 'unreliable' or 'outdated,' and 'when dissatisfied' (Kendal et al., 2005). To make inferences about

broader populations, one can use the social circle heuristic. For example, to judge prevalence of diseases in the general population one can search for occurrences of the diseases in one's immediate social environment (Hertwig et al., 2005). Social environments also guide choices between different socially relevant options. People tend to choose the option that is set as the default in a given society, resulting in a large percentage of organ donors in societies where one needs to opt out of organ donation and a small percentage where one needs to opt in (Johnson and Goldstein, 2003).

Decision and Choice: Luce's Choice Axiom

Timothy J Pleskac, Michigan State University, East Lansing, MI, USA

This article is a revision of the previous edition article by J.I. Yellott Jr, volume 13, pp. 9094–9097, © 2001, Elsevier Ltd.

Abstract

Luce's choice axiom (LCA) is a theory of individual choice behavior that has proven to be a powerful tool in the behavioral sciences for over 50 years. LCA is grounded in two fundamental properties: choice is probabilistic, and the probability of choosing an option from one set of alternatives is related to the probability of choosing the same option from a different set. This article reviews the basic properties of LCA. It also discusses crucial tests of predictions derived from LCA regarding the role of context. The historical connections of LCA and crucial applications of LCA are also reviewed.

Introduction

A subject in a psychology experiment (animal or human) identifies which of two stimuli are brighter; a diner at a restaurant selects a meal from a menu; an eyewitness determines a face in a lineup. These are all specific examples of a general behavior called 'choice,' where an individual selects one option from a larger set of alternatives.

Owing to the generality of choice behavior, many different areas of the social sciences have sought a mathematical description of choice. Luce's (1959) choice axiom (LCA) is one such description of individual choice behavior. As Estes (1997) describes it, Luce, in developing a theory of individual choice behavior, did not take the standard approach of psychology. Instead of working from the bottom up, accumulating empirical data on a phenomenon of interest and eventually arriving at a general theory of choice behavior, Luce took the approach of theoretical physics and worked from the top down. He employed intuition and reason to find a set of general assumptions that if true would allow the development of a theory and mathematical model useful for interpreting and understanding choice behavior. In short, LCA helped usher in the axiomatic method into psychology and, more broadly, the social sciences. Owing to this new approach is no doubt part of the reason why an early draft of the book and the ideas in it were referred to as the "red menace" (Estes, 1997).

Luce started with two basic tenets of individual choice behavior: (1) it is probabilistic; and (2) the probability of choosing an option from one set of alternatives is related to the probability of choosing the same option from a larger set of alternatives. The tenet that choice behavior is probabilistic is in contrast to assuming choice is deterministic. To understand this distinction, consider a situation where an agent chooses an option x from the set of alternatives T (e.g., possible entrees on a menu). Focusing on the special case of two-alternative forced-choice or paired comparison, deterministic theories assume a binary preference relation $\prec$ that is either true or false for any pair of alternatives, either $x \prec y$, $y \prec x$, or $x \sim y$ for all $x, y \in T$, where $\sim$ is indifference.

A probabilistic choice theory, like LCA, makes the more psychologically plausible assumption that it is only with some probability that an alternative is selected. Focusing again on a paired comparison, a probabilistic choice theory specifies a probability function $P(x,y)$ that maps each pair of alternatives into the closed interval [0,1]. LCA is a multi-alternative choice theory, so it is not limited to paired comparisons but is applicable in the more general choice situation specifying the probability that x will be chosen from the set T, $P_T(x)$. Regardless, as a probabilistic theory, LCA adheres to the axioms of probability theory. These axioms are:

$$1.\ \text{For } S \subset T, 0 \leq P_r(S) \leq 1$$

$$2.\ P_T(T) = 1$$

$$3.\ \text{If } R,\ S \subset T \text{ and } R \cap S = 0,\ \text{ then } P_T(R \cup S) = P_T(R) + P_T(S)$$

The probability axioms constrain each of the measures P_T. The problem is that the axioms themselves offer no connection between measures over different sets composed of some of the same alternatives; yet, such a connection seems necessary for a theory of choice. Anecdotally, the probability that one chooses pan-seared walleye from the dinner menu at a restaurant certainly seems related to the probability that he or she will choose the same entree from the smaller, reduced lunch menu. This observation motivates a second tenet of choice behavior: how decision makers select an option from a smaller set of alternatives is related to how they would choose when the same option is in the context of a larger set of alternatives and vice versa. LCA formalizes this assumption.

The Choice Axiom

The axiom has two parts.

Part 1:

$$\text{If } P(X,Y) \neq 0, 1 \text{ for all } x, y \in T, \text{ then for } R \subset S \subset T \quad P_T(R) = P_S(R) P_T(S) \qquad [1]$$

Part 2:

$$\text{If } P(X,Y) = 0 \text{ for some } x, y \in T, \text{ then for } S \subset T \quad P_T(S) = P_{T-\{x\}}(S - \{x\}) \qquad [2]$$

Working backward, Part 2 is more or less a housekeeping assumption. It allows alternatives that are never chosen in pairwise choices to be deleted from S without impacting the choice probabilities. If salted whitefish is never chosen in pairwise choices with trout, then in choices between salted whitefish, trout, and walleye, salted whitefish can be safely deleted, reducing the choice to trout or walleye.

Part 1 states that the probability of selecting the set of alternatives R (e.g., walleye or trout) from T is equal to the probability of selecting R from S (e.g., walleye, trout, or salmon) multiplied by the probability of selecting S from T. When $S = \{x, y\}$ then the probability measure P_S reduces to a pairwise choice probability mentioned earlier. In other words, Part 1 addresses the issue of formally relating the choice probabilities for subsets of T to those of T itself. Another way to see this is to rewrite eqn [1] as a conditional probability:

$$P_T(R/S) = P_S(R) = \frac{P_T(R)}{P_T(S)} \qquad [3]$$

where $R \subset S \subset T$ and $P_T(S) > 0$. Thus, the probability of selecting R from S equals the conditional probability that R is chosen from S when the full set T is available.

To be clear, LCA is not an additional probability axiom. Rather, it is an empirical hypothesis that has a number of strong consequences. These consequences have been tested, and in some places have been shown not to hold under specific circumstances. Nevertheless, LCA and the mathematical model it implies have proven quite useful in modeling choices whether they are higher level economic decisions or lower level perceptual choices. It has also motivated similar approaches in modeling probability judgments (Tversky and Koehler, 1994).

Implications

Most well known is that LCA implies that there is a numerical ratio scale v over T such that for every $x, y \in S \subset T$ the probability of choosing x can be found with the following mathematical model:

$$P_S(x) = \frac{v(x)}{\sum_{y \in S} v(y)}. \qquad [4]$$

Psychologically $v(x)$ is a response strength associated with the alternative x. One might see from eqn [4] that one measure of response strength is the observed choice probability $v(x) = P_T(x)$. Other scales can be created by multiplying $P_T(x)$ by a positive constant k, $v(x) = k \cdot P_T(x)$. This means that v is a ratio scale of response strength, a provocative idea in psychology that is beset with ordinal scales.

Equation [4] is an intuitive way to model choice probabilities, so much so that others have proposed it as a model of choice. For example, Bradley and Terry (1952) proposed a model consistent with eqn [4] for pairwise choices (see also Clark, 1957). This straightforward way to model choices via response strength also exposes why LCA has proven important in modeling choices in a variety of domains.

Using eqn [4], one can also see that

$$\frac{P(x,y)}{P(y,x)} = \frac{P_S(x)}{P_S(y)}. \qquad [5]$$

This result is because both sides of eqn [5] are equal to $\frac{v(x)}{v(y)}$. This relationship is sometimes called the *constant ratio rule*. The constant ratio rule is a probabilistic form of what is called independence from irrelevant alternatives (Arrow, 1951). It implies that when LCA holds for a set of alternatives T and its subsets, the ratio $P_S(x)/P_S(y)$ is independent of S. In other words, the ratio of the probability of choosing one alternative to the probability of choosing another should be constant regardless of the set of options (or context).

This constant ratio rule is revealing in terms of the strengths and weakness of LCA. A key strength is that pairwise choice probabilities can be predicted from choice probabilities observed in a larger set. A potential weakness is that psychologically the context of the situation (e.g., similarity to other choice alternatives) should impact the probability of choosing an option in some manner. Such a weakness speaks to the validity of LCA, and we will return to this idea in the validity section.

LCA also constrains the possible pairwise probabilities. This constraint is known as the product rule, which states that for alternatives x, y, and z.

$$P(x,y) \cdot P(y,z) \cdot P(z,x) = P(x,z) \cdot P(z,y) \cdot P(y,x). \qquad [6]$$

To see how the product rule works, note that the left-hand and right-hand sides contain complementary pairwise choice probabilities. Consequently, dividing the left-hand side by the right-hand side produces

$$\frac{P(x,y)}{P(y,x)} \cdot \frac{P(y,z)}{P(z,y)} \cdot \frac{P(z,x)}{P(x,z)} = 1. \qquad [7]$$

Each of the ratios of choice probabilities can, in turn, be rewritten as a ratio of response strengths by eqn [4]. This allows each response strength to be canceled off, resulting in the product of the ratios equaling 1. The product rule is another independence condition that implies the response strength for an alternative is the same regardless of the other alternative it is paired with. Just as with the constant ratio rule, the product rule identifies the strengths and potential weaknesses of LCA. The strength is that the product rule allows one to predict the pairwise choice probability $P(x,z)$ if $P(x,y)$ and $P(y,z)$ are both known. The weakness is that again psychologically it seems that the context matters. Again, the similarity between two alternatives seems like it should impact the response strength of an option.

Historical Connections

LCA has a number of connections to other choice models. Perhaps most prominent is the connection to L.L. Thurstone's (1927) law of comparative judgment. This theory assumes that alternatives have numerical psychological values that vary randomly from one choice occasion to another (i.e., the values are random variables). The decision maker is assumed to compare these values in order to make a choice. More precisely, if the psychological value of the alternatives $x_1, \ldots, x_N$ are the random variables $U_1, \ldots, U_N$, the probability of choosing x_i from any set S is the probability that U_i is currently the largest of the random variables $\{U_j : x_j \in S\}$. The

most prominent version of Thurstone's theory is Case V, which assumes the psychological values are normally, independent and identically distributed. This means U_i can be rewritten as $u_i + \varepsilon_i$, where u_i is a real constant (i.e., a scale value) and ε_i is normally distributed with a mean of 0 and variance of 1, $\varepsilon_i \sim N(0,1)$.

Luce (1959) showed that LCA and Case V make nearly identical predictions for pairwise choice probabilities: the numerical predictions were off by at most 0.02. In fact, if the differences between the psychological values have a logistic distribution rather than a normal distribution, then Thurstone's law of comparative judgment and LCA make identical predictions (Adams and Messick, 1957). What Holman and Marley (cited in Luce and Suppes, 1965) subsequently showed is that a logistic distribution of differences arises in Thurstone's (1927) framework if the normal random variables ε_i are replaced by independent random variables that have a double exponential probability distribution.

Yellott (1977), in the spirit of Luce's top-down axiomatic approach, identified an intuitively plausible assumption that would lead one to conclude the random variables ε_i are double exponentially distributed. The assumption is grounded in the property that the asymptotic distribution of the maximum of n independent, identically distributed random variables is the double exponential when the underlying distribution has an upper exponential tail. Using this property, Yellott proposed a thought experiment in which there are three basic alternatives, for example, beverages on a table: coffee, tea, and milk. Instead of one cup of each on the table, consider a situation like a party where there are n identical cups of coffee, n cups of tea, and n glasses of milk. One would expect that the probability of choosing any one of the beverages should be independent of n or how many replicas there are. In fact, if this invariance assumption is met, then the distribution in a Thurstone model must be a double exponential and, as a result, LCA must hold. In the words of Luce (1977), "Yellott's condition is so compelling that this theorem means Thurstone's model … and the choice axiom stand or fall together" (p. 218).

LCA also connects with a number of other models in experimental psychology. This came primarily via what is called the similarity choice model (Estes, 1997). This model is a generalization of the choice model in eqn [4] that Luce (1959) developed to account for response bias and later fully developed in Luce (1963) (see also Shipley, 1960). The similarity choice model decomposes the response strength v into two ratio scales representing two constructs of high interest to psychologists: discriminability and response bias. To see the extension, consider the situation where a participant in a psychology experiment must choose a response R_j upon presentation of a stimulus V_i (e.g., identify a letter upon the presentation of an obscured letter stimulus). The similarity choice model states the response probability is

$$P_{i,j} = \frac{M_{i,j} \cdot b_j}{\sum_k M_{i,k} \cdot b_k}. \qquad [8]$$

The scale value $M_{i,j}$ represents the similarity between stimulus V_i and the stimulus corresponding with the response j, V_j. The other scale value, b_j, measures a subject's bias to choose response j regardless of the stimulus.

It should be noted that the similarity choice model is a generalization of the choice model (eqn [4]), but not necessarily the axiom itself (Luce, 1963). Despite this restriction, the similarity choice model can easily have some of the same context-free assumptions of LCA. The similarity choice model provided researchers with an alternative and more convenient means to model discriminability and response bias than with signal detection theory (Tanner and Swets, 1954). This convenience facilitated the incorporation of the similarity choice model as a choice rule into more complex models of cognitive processes including identification, recognition memory, categorization, and categorization learning (see Estes, 1997).

Validity of LCA

The value of the axiomatic approach that underlies LCA is that it establishes precise and testable conditions that help establish when a theory is applicable and when it is not. In the case of LCA, examples were almost immediately identified that questioned its validity.

One of the first examples came from Gerald Debreu (1960) in his published review of *Individual Choice Behavior*. (A famous adaptation of Debreu's example is the red-bus-blue-bus problem in transportation research (Train, 2003).) The example is as follows. Consider a classical music lover who is choosing between a recording of the Debussy quartet (option D) and two different recordings of Beethoven's Eighth Symphony (option B_1 and option B_2). For this example, assume the two Beethoven recordings are of equal quality (e.g., played by the same orchestra, but under the direction of different conductors). Let us assume the music lover is torn between adding a Debussy or a Beethoven recording to his collection. Therefore, in pairwise choices $P(B_1,B_2) = P(D,B_1) = P(D,B_2) = 1/2$. LCA thus implies that when presented with the set S of all three options $\{D, B_1, B_2\}$ simultaneously that $P_s(D) = 1/3$. However, this conclusion is not quite right intuitively. When the choice is between all three, it seems that the choice is between Debussy or Beethoven. Put differently, $P_S(D)$ should remain closer to 1/2, while choice probability for the two Beethoven recordings should be split equally, moving them closer to 1/4. Empirically, at least in preferential tasks, this is what happens. Tversky (1972) called this the similarity effect. He found violations when subjects were asked to make choices between college applicants and gambles. However, the violations in a perceptual task of judging dot numerosity were not statistically significant.

The similarity effect is inconsistent with the constant ratio rule of LCA (eqn [4]). The implication of the similarity effect is actually stronger in that it is inconsistent with any probabilistic choice theory that assumes choice probability is a monotone function of scale values also known as simple scalability models (Tversky, 1972). Note the similarity between alternatives also impacts pairwise choice probabilities and leads to violations of the product rule and other independence assumptions (Rumelhart and Greeno, 1971; Tversky and Russo, 1969).

Generalizations of LCA can be developed to account for the similarity effect. For example, Tversky (1972) proposed an alternative choice process called elimination by aspects where alternatives are sets of attributes or aspects. Figure 1 depicts

Figure 1 A graphical representation of three alternatives each composed of a set of unique and shared aspects.

a three-alternative set $T = \{a, b, d\}$. The aspects α, β, and δ are unique to alternatives a, b, and d, respectively. The other aspects $\alpha\beta$, $\alpha\delta$, and $\beta\delta$ are shared. Each aspect has a scale value u representing its utility. Because of the elimination by aspect assumption of the theory, aspects shared among all alternatives are not used in this choice rule, hence the central area in Figure 1 is unlabeled.

The basic idea in the theory is that an aspect is attended to with some probability (e.g., Beethoven). This probability is proportional to its utility relative to the sum of all the utilities K. For example, the probability of selecting $\alpha\beta$ is $u(\alpha\beta)/K$. Alternatives that do not have that aspect (e.g., d) are then eliminated and the probability of selecting say a is the pairwise choice probability scaled from the remaining aspects

$$P(a,b) = \frac{u(\alpha) + u(\alpha\delta)}{u(\alpha) + u(\alpha\delta) + u(\beta) + u(\beta\delta)}. \qquad [9]$$

In other words, elimination by aspects is consistent with one's intuitive reaction to Debreu's (1960) Debussy/Beethoven example: after an alternative is eliminated, choice probability gets divided among the remaining alternative.

If an aspect is attended to that is unique to a particular alternative (e.g., a), then the corresponding alternative (e.g., a) is selected with probability 1. Thus, the probability of selecting alternative a from T is

$$P_T(a) = \frac{u(\alpha) + u(\alpha\beta)\cdot P(a,b) + u(\alpha\delta)\cdot P(a,d)}{K}. \qquad [10]$$

Elimination by aspects is one hypothesis of how the similarity between the alternatives (i.e., shared aspects) interacts with the choice process. Using Figure 1, one can also see how elimination by aspects is a generalization of LCA: if alternatives are pairwise disjoint (i.e., no shared aspects between pairs of alternatives), then the predicted choice probabilities are consistent with LCA (Tversky, 1972).

More broadly, the similarity effect demonstrates that context matters: the response strength of an alternative depends on the options that are in the choice set. Over the years, other context effects have been identified and studied that further attest to the importance of context (Rieskamp et al., 2006). A second context effect that questions the validity of LCA (as well as elimination by aspects) is known as the attraction effect. The attraction effect can be illustrated with an example from Simonson and Tversky (1992). They gave one group of subjects a choice between \$6 and a nice Cross pen. The pen was chosen by 36% of the subjects, while the remaining 64% chose \$6. A second group was given a choice between three options: \$6, a nice Cross pen, or another less attractive pen. As one might expect, only 2% chose the less attractive pen. Yet, the mere addition of this asymmetrically dominated alternative boosted the proportion of subjects who chose the Cross pen to 46% (an increase of 33%). This behavior no doubt well known among marketers and salespeople does not seem quite right from the view point of LCA and, for that matter, most probabilistic theories of choice: adding an alternative to a choice set of even minuscule value should reduce choice probabilities for the all the alternatives, not increase them. This condition is known as regularity. Stated formally, for $x \in S \subset T$, $P_S(x) > P_T(x)$. The attraction effect demonstrates that in particular situations, individuals violate regularity.

A third context effect is the compromise effect. This effect can be demonstrated with another example from Simonson and Tversky (1992), where participants made choices between hypothetical cameras. Camera A was high in quality and price; Camera B was low in quality and price; and Cameral C had intermediate quality and price. In pairwise probabilities, $P(A|\{A, C\}) = P(C|\{A, C\})$. However, when Camera B at the other extreme is added to the choice set, $P(C|\{A, C, B\}) > P(A|\{A, C, B\})$. The compromise effect is another violation of independence from irrelevant alternatives. It questions the validity of LCA as well as elimination by aspects (for a proof, see Rieskamp et al., 2006).

These empirical effects identify limitations of LCA as a model of human choice behavior. In particular, they demonstrate a third tenet of choice behavior is that context does matter, and it shapes how individuals value an alternative. There are different psychological explanations for the role of context. Nevertheless, LCA and the choice rule that it implies have persisted as a useful model of individual choice behavior. There are at least two reasons for this. First, the basic idea that choice probability is monotonic with a response strength is intuitively quite plausible and one that has generally persisted even as alternative models have been proposed to account for context effects. Second, the axiom and the choice rule are elegantly simple, allowing for both easy implication and easy explanation.

Applications in Preferential Decisions

As the previous section examining the validity of LCA illustrates, there has been great interest in applying LCA to preferential choices. These are choices made over money and other alternatives (e.g., cameras, records, commuting routes, etc.) where there is no objectively correct answer. Luce (1959) very much anticipated applications of LCA and the choice rule in this domain, but great strides were made when (McFadden, 1976, 2001) developed an economic version of Luce's choice model in the *multinomial logit* model. Formally, the probability of choosing alternative x from set S is

$$P_S(x) = \frac{\exp[u(x)]}{\sum_{y \in S} \exp[u(y)]}, \qquad [11]$$

where $u(x)$ is the utility of alternative x and is a linear function of the attributes of x.

The multinomial logit model proved useful in economic data analysis, but it is also connected to what are called random utility models. This connection perfectly echoes the connection between LCA and Thurstonian choice models discussed earlier. Random utility models akin to Thurstonian models assume the utility of an alternative is a random variable. McFadden (1976), independently from Yellott (1977), showed that if the linear combination of attributes has an error component that is identically and independently distributed following an extreme value distribution (i.e., double exponential), then the result is the multinomial logit model. The multinomial logit model has become one of the most common random utility models (Train, 2003).

LCA has also contributed heavily in the further development of descriptive theories of preferential choice (Rieskamp et al., 2006). In this area, the formal attributes of LCA have proven indispensable in forming testable hypotheses about how individuals make a choice. Doing so has validated the core tenets of LCA (i.e., choice is probabilistic, and there is a connection between the propensity to choose alternatives between contexts). At the same time, as discussed in the previous section, LCA very much helped uncover other tenets such as the context dependence of choice. Psychologists and decision scientists have, in turn, sought to develop other formal theories that better account for these tenets. Examples (among others) include the context-dependent advantage model (Tversky and Simonson, 1993), decision field theory (Roe et al., 2001), and the leaky accumulator model (Usher and McClelland, 2004). The latter two theories perhaps represent the greatest departure from LCA in that they are grounded in a sequential sampling account of choice. Such a move allows for the theories to describe both choice probabilities and the time taken to make a choice. This is an important step as perhaps a fourth tenet of choice behavior is that the process of making a choice takes time, a property LCA is silent on.

One final application of LCA in preferential choices comes in the area of strategic games and game theory (McKelvey and Palphrey, 1995). Strategic games are situations when entities must decide how to act during interactions with other entities. Examples include two tennis players opposing each other in a match, roommates waiting for the other to purchase kitchen supplies, or research and development expenditures by competing pharmaceutical companies. These are all examples of interactions where how one entity decides to act affects the outcomes of the other and vice versa. This interaction is what distinguishes strategic games from the individual decisions where the outcomes an individual receives do not depend on the decisions of others. In game theory, each individual chooses among an action or strategy based on the utility of the outcomes that are expected to come from employing that strategy. Typically, the choice between strategies in game theory is deterministic. McKelvey and Palphrey (1995) adapted the multinomial logit model (eqn [11]) to move away from the deterministic assumption to one where players probabilistically choose among their strategies and assume their opponents do so as well.

The advantage of adapting a probabilistic choice rule in strategic games is twofold. The first advantage is that the probabilistic choice rule provides a more psychologically plausible assumption than a deterministic selection of a strategy. This allows the best equilibrium strategy to be played more often than others (but not always). The second and related advantage is that this can aid in data analysis of games where observed behavior is probabilistic, allowing measurement of interesting phenomena like learning during repeated play.

Applications in Learning

Luce (1959) also discussed LCA's application in modeling learning. Learning has long been of interest in the area of choice whether it be modeling the behavior of rats in a T-maze as they learn a route to food or more recently a participant in a psychology experiment choosing repeatedly between gambles that deliver a reward and/or punishment with unknown probabilities. Luce's idea called the beta model postulated operators that adjust the response strength of each alternative (e.g., $v(x)$) rather than adjusting the choice probabilities. More formally, during a learning experiment on each trial n, each alternative $x \in S$ has a response strength $v_n(x)$. If alternative x was selected on trial n, then the response strength for trial $n+1$ is updated. To make a choice on the trial $n+1$, the individual then uses the choice rule described in eqn [4]. Thus, in the beta model, LCA is assumed to hold on any given trial, but between trials the probability changes via adjustments in response strength.

This same basic idea is implemented in recent reinforcement learning algorithms that have become popular in a variety of areas including machine learning, control theory, game theory, and neuroscience. Perhaps the closest relation is with the Q-learning algorithm. According to this algorithm, after an agent selects an alternative x, the agent uses the experienced reward to update an expectation $Q(x)$ for alternative x (Sutton and Barto, 1998). To make a choice between the available alternatives in the set S, the algorithm uses the following rule sometimes called softmax:

$$P(x) = \frac{\exp[Q(x)/\tau]}{\sum_{y \in S} \exp[Q(y)/\tau]}. \tag{12}$$

The rule is a particular instance of eqn [4]. The parameter τ moderates the degree to which the agent chooses the alternative with the largest expectation. As τ increases, the agent is less likely to choose the option with the largest expectation and instead explore other alternatives. Note unlike the similarity choice model (eqn [8]), τ is not specific to the alternative, so it characterizes general exploration rather than a bias to a specific alternative. In general, this means the probabilistic choice rule provides a mechanism to trade off between selecting an alternative that provides an immediate payoff (exploit) or selecting an alternative that provides information to develop an expectation about future choices (explore). Neuroscientists are beginning to understand the neural basis of these learning mechanisms (Niv, 2009). The softmax expression, in particular, has proved useful in beginning to understand the neural mechanisms underlying the trade-off between exploration and exploitation (Daw et al., 2006). Finally, these learning mechanisms with the softmax rule are being integrated into larger cognitive architectures (Fu and Anderson, 2006).

Future Directions and Conclusion

LCA challenged conventional theories of choice to move from a deterministic account to a probabilistic one. In so doing, LCA has proved to be a power and useful tool in the modeling toolboxes of social and cognitive scientists for over 50 years. A search among scholarly articles is certain to reveal its vast impact. Yet, there are still areas that are left to be explored with LCA and the accompanying mathematical model of choice. Behaviorally, one area that Luce (1959) discussed and has still remained largely unexplored is that of ranking alternatives. Luce (1959) proposed one way to adapt LCA to ranking where the individual essentially makes a series of covert choice first picking, say the best alternative from the set, then the second best alternative from remaining items, and so on. This is called forward ranking. Another procedure, called backward ranking, works the opposite direction: picking the worst, next worst, and so on. Both procedures seem intuitively plausible; however, forward and backward ranking do not lead to the same solution (Luce, 1959). For current work in this area see Marley and Louviere (2005) and Lee et al. (2012).

As decision theorists continue to reconcile with the theoretical implications of probabilistic choice behavior, there are certainly more and more challenges. One challenge is a psychological one, which is to continue to develop a theory of choice behavior that is grounded in some of the core tenets of LCA (i.e., choice is probabilistic and that there is a relationship in how people choose between contexts), but also reflects other important properties like the context dependence and time course of choice. A second challenge is a neural one, which is to understand the neural circuitry underlying choice behavior (Gold and Shadlen, 2007). A final challenge is a statistical one, which is to develop appropriate statistical methodology to test probabilistic theories of choice-appropriate variability in choice behavior (Regenwetter et al., 2011). These are just some of the challenges we face. Regardless, LCA via its simple elegance is certain to continue to be an invaluable tool in helping us understand individual choice behavior.

Decision and Choice: Random Utility Models of Choice and Response Time

Hans Colonius, Carl von Ossietzky Universität Oldenburg, Oldenburg, Germany
Anthony AJ Marley, University of Victoria, Victoria, BC, Canada

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Horse race random utility models for choice and response time are studied, and conditions on the observable choice probabilities and decision times necessary and sufficient for a random utility representation are investigated. We state conditions for stochastic independence of option chosen from time of choice. Context-free accumulator models, like the linear ballistic accumulator model, are presented as horse race models with additional structure. Models with multiplicative and with additive drift rate variability are discussed.

Introduction

The task of choosing a single 'best' option from some available, potentially infinite, set of options A has received considerable study in psychology and economics. *Random utility models* of choice account for the stochastic variability underlying these choices (i.e., the same choice is not necessarily made on repeated presentations of the same set of options) by assuming that there exists a random variable, $U(x)$ for each option, x and a joint probability measure for these random variables such that the probability of choosing a particular option, x from the set of available options is equal to the probability that $U(x)$ takes on a value greater than the values of all other random variables (*see* Decision and Choice: Luce's Choice Axiom). The basic choice paradigm is extended here by considering, in addition to the option chosen, the point in time that a choice is made from the set of available options. The random utility model can be tailored to cover this situation by replacing the utility variable, $U(x)$ by $T(x) = \phi[U(x)]$ (ϕ, some monotonically decreasing transformation of the values of U into the nonnegative real numbers), where $T(x)$ can be interpreted as the decision time for choosing option x, and by replacing the maximum utility rule by a minimum decision time rule: the option chosen is the one that happens to be associated with the minimum choice (or decision) time with respect to all options in the available set. This model will be referred to as a *horse race random utility model*. Over the past 15 years, psychologists and economists have extended the random utility framework to tasks where a person might be asked to select the 'worst' option, or the 'best' and 'worst' option, from some available choice set. For reasons of space, we do not present parallel results for these cases, but see the results in Hawkins et al. (2014) and the summaries in Marley and Flynn (2015) and Marley and Regenwetter, (in press).

A number of questions arise in the study of horse race random utility models for choice and response time, some of which have received partial answers: (1) What conditions on the observable choice probabilities and decision times are necessary and sufficient for a random utility representation? (2) What are the consequences of assuming stochastic independence between the time of choice and the identity of the option chosen, and which assumptions on the joint distribution function imply this independence? (3) What are possible generalizations to other choice paradigms? The presentation here is partly based on Marley (1989) and Marley and Colonius (1992); those papers present and cite related results that are not explicitly referred to in the following.

Horse Race Random Utility Models

Let $A = \{x, y, \ldots\}$ be a *finite* set of potential choice options (for an extension of the theory to infinite choice sets see Resnick and Roy, 1992); the subset X of A containing at least two elements is the currently available choice set. T_X is a random variable denoting the time at which a choice is made; and B_X is a random variable denoting the element chosen from X. For $t \geq 0$,

$$B_X(x;t) = Pr[B_X = x \cap T_X > t] \qquad [1]$$

is the probability that option x is chosen as the best from X after time t, and $\{B_X(x;t) : x \in X \subseteq A\}$, or (A, P) for short, is called a *joint structure of choice probabilities and response times*. (A, P) is called *complete* if it is defined for all subsets of X of A with $|X| \geq 2$.

A complete joint structure of choice probabilities and response times, (A, P) is said to satisfy a *horse race random utility model* if there exists a probability measure, $Pr_X[\ ]$ for the collection of nonnegative random variables, $\{T(x): x \in X\}$ such that, for all $X \subseteq A$ with $|X| \geq 2$,

$$B_X(x;t) = Pr_X[t < T(x) < T(y) : y \in X \backslash \{x\}] \qquad [2]$$

For simplicity, all distributions are assumed to be absolutely continuous, i.e., they must possess a density function; however, as observed in Resnick and Roy (1992), absolute continuity is not necessary for the results cited here. The representation eqn [2] is of the form given in eqn [1] with $T_X = \min\{T(y): y \in X\}$. Also note that with

$$\begin{aligned} B_X(x) &= \lim_{t \downarrow 0} Pr_X[t < T(x) < T(y) : y \in X \backslash \{x\}] \\ &= Pr_X[T(x) < T(y) : y \in X \backslash \{x\}] \end{aligned}$$

the collection of choice probabilities, $\{B_X(x) : x \in X \subseteq A\}$ constitutes a *system of choice probabilities* with

$$B_X(x) = Pr_X[T(x) = \min\{T(y) : y \in X\}]$$

satisfying a *random utility representation* with min replacing the usual max.

In this article the problem of finding conditions on the – at least theoretically – observable choice probabilities and

response time distributions, which are necessary and sufficient for the existence of a particular representation in terms of a collection of underlying random variables, is referred to as a *characterization problem*.

General characterization problem. Given a (complete) joint structure of choice probabilities and response times what conditions on the (survival) functions, $B_X(x;t)$ are necessary and sufficient for the existence of a (possibly dependent) horse race random utility representation for that joint structure?

A complete answer to this problem is still open. However, a number of results in special cases have been found.

Representation by Independent Random Variables

The following is a partial answer to the general characterization problem:

Theorem 1 (Marley and Colonius, 1992).

a. For a collection of choice probabilities and response times, $\{B_X(x;t): x \in X\}$, on a fixed set X with $|X| \geq 2$, there exist independent random variables, $T(x)$, $x \in X$, with unique distributions, such that eqn [2] holds, provided $B_X(x;t)$ is absolutely continuous and positive for all $t \geq 0$.
b. A complete joint structure of choice probabilities and response times (A, P) can be represented by an independent horse race random utility model, with unique distributions, if the conditions of (a) hold and

$$\left[\sum_{y \in X} B_X(y;t)\right]^{-1} (\mathrm{d}/\mathrm{d}t) B_X(x;t) \qquad [3]$$

is independent of $X \subseteq A$ for all $t \geq 0$.

Thus, given the above regularity conditions on the response time distributions, part (a) shows that *any* set of choice probabilities and response times on a *fixed* finite set, X can be represented by *independent* random variables such that the horse race eqn [2] holds; and part (b) gives sufficient conditions for a common representation across all subsets of A. Townsend (1976) develops a related result in the context of parallel–serial processing analysis. Thus, the general characterization problem is still unsolved leaving open the possibility that for some joint structures no independent representation over all subsets X exists.

Some of the distributions, but not all, in the above solutions may be *improper*, i.e., they may have positive measure at infinity implying an infinite decision time for that alternative, even if the distribution of response time, T_X is finite almost surely. Jones and Dzhafarov (2014) present related interpretations and further falsifiability results for horse race and other models of choice and response time.

The above framework has natural extensions to subset choice (Marley and Colonius, 1992) and to the worst and best–worst choice (Marley and Regenwetter, in press). Also, in the theory of competing risks (e.g., David and Moeschburger, 1978) the 'event' associated with each $x \in X$ is reinterpreted as a *cause* (e.g., of failure or death) and thus the selection of $x \in X$ then corresponds to the cause associated with x being the first to occur when X contains the possible causes. This leads to *cause-specific* (or *crude hazard rate*) interpretations of the results and related *nonidentifiability* issues (Marley and Colonius, 1992).

Independence of Option Chosen from Time of Choice

A classic model for best choice is *Luce's choice model* (*see* Decision and Choice: Luce's Choice Axiom), also called the *multinomial logit (MNL) model* (Marley and Regenwetter, in press). That model holds for a system of choice probabilities, $\{B_X(x) : x \in X \subseteq A\}$ provided there is a ratio scale b on A such that for $B_X(x) \neq 0, 1$

$$B_X(x) = \frac{b(x)}{\sum_{y \in X} b(y)} \qquad [4]$$

For simplicity in the following, we assume that all choice probabilities are nonzero. The result can be generalized when this is not the case by adding a connectivity and a transitivity condition (Luce, 1959: Theorem 4, p. 25).

Theorem 2 (Marley and Colonius, 1992)

Consider a (complete) independent horse race random utility model, (A, P) where for each $x \in X \subseteq A$ with $|X| \geq 2$, $B_X(x;t)$ is positive and absolutely continuous for all $t > 0$. If T_X is stochastically independent of B_X, then the choice probabilities satisfy Luce's choice model.

Given the known limited empirical validity of Luce's choice model in empirical preference situations, this result implies that one must study *dependent* horse race random utility models and/or drop the assumption of independence between T_X and B_X. We now present results for such generalizations.

Generalized Stable Survival Functions

A large class of (possibly) dependent horse race random utility models based on extreme value distributions can be generated from the concept of a *generalized stable survival function*. For simplicity, in this section, assume $A = \{x_1, \ldots, x_n\}$. We call

$$P_A(t_1, \ldots, t_n) = Pr[T(x_1) > t_1, \ldots, T(x_n) > t_n)$$

a *(multivariate) survival function*. P_A is called *generalized stable* if there is a strictly monotone decreasing function, η and a constant, $\mu > 0$ such that for all $\alpha > 0$, $t_i \geq 0$, $i = 1, \ldots, n$,

$$(\eta \circ P_A)(\alpha t_1, \ldots, \alpha t_n) = \alpha^{\mu} (\eta \circ P_A)(t_1, \ldots, t_n) \qquad [5]$$

where $\circ$ denotes the concatenation of functions. Letting $G_A = (\eta \circ P_A)$, this amounts to

$$G_A(\alpha t_1, \ldots, \alpha t_n) = \alpha^{\mu} G_A(t_1, \ldots, t_n)$$

i.e., G_A is homogeneous of degree μ. Furthermore, a survival function P_A is called a *strictly monotone transform of a generalized stable survival function*, Q_A if there is a strictly monotone increasing function γ (of the random variables associated with Q_A) with $\gamma(0) = 0$, $\gamma(\infty) = \infty$ such that for $t_i \geq 0$, $i = 1, \ldots, n$,

$$P_A(t_1, \ldots, t_n) = Q_A[\gamma(t_1), \ldots, \gamma(t_n)]$$

Theorem 3 (Marley, 1989)

Any horse race random utility model that is generated by a strictly monotone transform of a generalized stable survival function is such that T_X is stochastically independent of B_X for any $X \subseteq A$.

Resnick and Roy (1992: Section 5) construct an example, which shows that the converse of this result does not hold in general, i.e., independence between T_X and B_X does not lead back to the class of generalized stable survival functions. However, Robertson and Strauss (1981) show that the converse is true if the survival function, P_A (or some strictly monotone transformation of it) belongs to the generalized Thurstone class: for $t_i \geq 0$, $i = 1, \ldots, n$,

$$P_A(t_1, \ldots, t_n) = P(u(x_1)t_1, \ldots, u(x_n)t_n)$$

where $u(x_i) \geq 0$ and P is a survival function that is independent of A.

Marley (1989) uses generalized stable survival functions to extend a large class of frequently applied random utility models for choice to models of choice and response time; these models of choice include McFadden's *generalized extreme value* class, Tversky's *elimination by aspects* model, and Strauss's *general feature* model. However, by the above results, all these models predict the independence of the choice made and the time to make it, and so, in particular, that the response time distribution is the same for all choices. Given that the latter condition is not satisfied by various data (Hawkins et al., 2014), we now turn to related models that do not have this property.

The results above were stated in terms of the *survival* form

$$B_X(x; t) = \Pr(B_X = x \text{ and } T_X > t)$$

If we now let $B_X(x,t)$ denote the probability that option x is chosen *at or before* time t (note the change of the semicolon ; to a comma ,), then those results can be written equally well in the *cumulative* form

$$B_X(x, t) = \Pr(B_X = x \text{ and } T_X \leq t) \quad [6]$$

Since most response time models are written in terms of such cumulative distributions, we will use the latter form in the remaining sections.

Context-Free Linear Accumulator Models

Context-free accumulator models are essentially horse race random utility models with additional structure imposed on the properties of the random variables; later we summarize context-dependent accumulator models. Here, we discuss the *linear ballistic accumulator* (LBA) model (Heathcote and Love, 2012). Like other multiple accumulator models, the LBA is based on the idea that the decision maker accumulates evidence in favor of each choice, and makes a decision as soon as the evidence for any choice reaches a threshold amount. The time to accumulate evidence to threshold is the predicted decision time, and the response time is the decision time plus a fixed offset (t_0), the latter accounting for processes such as response production. The LBA shares this general evidence accumulation framework with many models (Busemeyer and Rieskamp, 2013; *see* Diffusion and Random Walk Processes) but has a practical advantage – namely, the computational tractability afforded by having an easily computed expression for the joint likelihood of a given response time and response choice among any number of options.

In the following sections, we consider two classes of LBA – the first class relates in a natural way to the models already presented, the second class agrees with the assumptions in the original development of the LBA. We first summarize context-independent models, and then summarize context-dependent extensions; we ignore the fixed offset, (t_0).

Multiplicative Drift Rate Variability

Let Δ be a random variable on the positive real numbers; this will be the distribution of the (multiplicative) drift rate variability, where *drift rate* is the rate of accumulation of evidence. Let, for $r > 0$,

$$\Pr(\Delta \leq r) = G(r) \quad [7]$$

where G is a cumulative distribution function (CDF). Let b denote the threshold, x a typical choice option with drift rate $\mathrm{d}(x)$, and Σ a random variable on $[0,A]$ with $A \leq b$; this will be the distribution of the start point of the evidence accumulation. Let, for $h \in [0,A]$,

$$\Pr(\Sigma \leq h) = H(r)$$

where H is a CDF.

For option x, the start point has distribution, Σ and the drift rate has distribution, $\Delta\mathrm{d}(x)$. We assume that the samples of Σ and Δ for different values of x are independent, which we denote by Σ_x and Δ_x; thus, the subscripts do not imply dependence on x beyond the assumption of independent samples for different values of x. Then, with b_x denoting the random variable for the time taken for the LBA with (mean) drift rate, $\mathrm{d}(x)$ to reach threshold, we have

$$\Pr(b_x \leq t) = \Pr\left(\frac{b - \Sigma_x}{\Delta_x \mathrm{d}(x)} \leq t\right) \quad [8]$$

The major LBA applications to date have assumed that the start point variability is given by a random variable, p with uniform distribution on $[b-A, b]$, in which case eqn [8] can be rewritten as

$$\Pr(b_x \leq t) = \Pr\left(\frac{p_x}{\Delta_x \mathrm{d}(x)} \leq t\right) \quad [9]$$

Then the choice and response time representation, $B_X(x,t)$ of eqn [6] holds with $T_X = \min\{b_\gamma: \gamma \in X\}$.

The above representation is a perfectly plausible multiplicative LBA model for *any* cumulative distribution G on the nonnegative reals and H on $[0,A]$ with $A \leq b$. However, a major argument advanced for LBA models is their computational tractability in terms of *probability density functions* (PDFs) and CDFs. In particular, it is usually assumed that the accumulators are independent, and therefore the main need is for the PDF and CDF of eqn [9] to be tractable. We summarize the components of the CDF corresponding to that expression, and then summarize what is known about such forms.

With p, the uniform distribution on $[b-A, b]$, and the CDF of G given by eqn [7], standard calculations show that $Pr(b_x \leq t)$ of eqn [9] can be written in terms of: the constants b and A; the mean of the distribution G when truncated to the interval, $[b/t\ \mathrm{d}(x),\ b-A/t\ \mathrm{d}(x)]$; and the values of $G[b-A/t\ \mathrm{d}(x)]$ and $G[b/t\ \mathrm{d}(x)]$ (Marley and Regenwetter, in press). Closed forms are known for the first quantity for various CDFs on the nonnegative reals, including for Gamma, inverted Beta, Fréchet, and Levy distributions (Nadarajah, 2009). However, one of the major motivations for the LBA framework was to achieve easily computable forms for the joint distribution of choice

probabilities and choice times – i.e., for eqn [6]. In addition to independence, this requires the PDFs corresponding to the CDFs, above, to be easily computable. Ongoing research is exploring the extent to which this is the case for various distributional assumptions. For example, Heathcote and Love (2012) develop and test the tractable *lognormal race*, which has the form: for each option x,

$$\Pr(\mathrm{b}_x \le t) = \Pr\left(\frac{S_x}{D_x} \le t\right)$$

where S_x is the distribution to the boundary and D_x is the drift rate distribution, with each being lognormally distributed.

Relation of Multiplicative LBA Models with No Start Point Variability and Fréchet Drift Rate Variability to Luce (MNL) Models

We now present a multiplicative LBA with no start point variability and Fréchet drift scale variability that leads to the Luce (MNL) model for the best choice; parallel results hold for the worst and best–worst choice (Marley and Regenwetter, in press). Consider the special case of eqn [9] where there is no start point variability, i.e., $A = 0$, and so p has a constant value, b; in this case, without loss of generality, we can set $b = 1$. Then eqn [9] reduces to

$$\Pr(B_x \le t) = \Pr\left(\frac{1}{\Delta \mathrm{d}(x)} \le t\right)$$

We also assume that Δ has a Fréchet distribution, i.e., there are constants α, $\beta > 0$ such that, for $r \ge 0$,

$$\Pr(\Delta \le r) = G(r) = e^{-(\alpha r)^{-\beta}} \qquad [10]$$

Then eqn [6] is (remember that the subscript on Δ_z indicates independent samples, not other dependence on z):

$$B_X(x,t) = \Pr\left(\frac{1}{\Delta_x \mathrm{d}(x)} = \min_{z \in X} \frac{1}{\Delta_z \mathrm{d}(z)} \le t\right) \qquad [11]$$

For $t \ge 0$, let $F(t) = 1 - \exp - (\sum_{z \in X} \mathrm{d}(z)^{\beta})(\alpha t)^{\beta}$. Then routine calculations (paralleling those in Marley, 1989) give: for $X \subseteq A$ and $x, y \in X$,

$$B_X(x;t) = \frac{\mathrm{d}(x)^{\beta}}{\sum_{z \in X}^{n} \mathrm{d}(z)^{\beta}} F(t) \qquad [12]$$

The choice probabilities, $B_X(x)$ are given by this formula in the limit as $t \to \infty$, i.e., as $F(t) \to 1$, which shows that they satisfy Luce's choice model, eqn [4], with $b(z) = d(x)^{\beta}$. Now, for $z \in A$, let $u(z) = \ln \mathrm{d}(z)$, $\varepsilon_z = \ln \Delta_z$. Then the form for the choice probabilities can equally well be written as: for all $x, y \in X \in D(A)$,

$$B_X(x) = \Pr\left\{u(x) + \varepsilon_y = \max_{z \in X}[u(z) + \varepsilon_z]\right\} \qquad [13]$$

However, given that Δ_z and $\Delta_{p,q}$ are generated by Fréchet drift rate variability, i.e., eqn [10], we have that $\varepsilon_z = \ln \Delta_z$ and $\varepsilon_{p,q} = \ln \Delta_{p,q}$ satisfy extreme value distributions (with, in this case: for $-\infty < t < \infty$ $\Pr(\varepsilon_z \le t) = \exp - (\alpha e^t)^{-\beta}$ and $\Pr(\varepsilon_{p,q} \le t) = \exp - (\alpha e^t)^{-\beta}$). Under these conditions, eqn [13] corresponds to the usual representation of Luce's choice model as a random utility model (Marley and Louviere, 2008, used the case $\alpha = \beta = 1$). Note that β is not identifiable from the choice probabilities, but it is, in general, identifiable when response times are also available (though the form predicted for the response time distribution is not suitable for data).

As already shown by eqn [12], this model has the property that the option chosen is independent of the time of choice; that property would not hold for (most) distributions other than the Fréchet for drift scale variability, nor does it hold when the above model is extended to include start point variability.

Additive Drift Rate Variability

In contrast to the multiplicative drift rate model presented above, the *LBA model* assumes *additive* drift rate variability generated by independent normal random variates, truncated at zero – i.e., constrained to be nonnegative (Heathcote and Love, 2012). This model is a horse race random utility model, but does not have the undesirable property that the choices made and the time to make them are independent. Nonetheless, it has been shown to make extremely similar predictions for the best, worst, and best–worst choice probabilities to those made by the multiplicative LBA model with no start point variability and Fréchet drift scale variability (Hawkins et al., 2014). The derivations for this model exactly parallel those for the multiplicative LBA model, above, with $\Delta \mathrm{d}(x)$ replaced by $\mathrm{trunc}[D_z + \mathrm{d}(z)]$, with a major advantage of the additive model being that all formulas for CDFs and PDFs are computationally very tractable when the start point distribution is uniform. Marley and Regenwetter (in press) briefly summarize recent applications of this model to some standard data on the best, worst, and best–worst choice and its extension to handle context effects in the best choice and response times.

Context-Dependent Models of Response Time and Choice

As far as we know, there is no formal definition of what it means for a set of (theoretical or empirical) choice probabilities to demonstrate a *context effect*. The general usage of that term appears to be that the choice probabilities are not consistent with either a *random utility* or a *constant utility* representation as defined in Chapter 10 of Suppes et al. (1989). Busemeyer and Rieskamp (2013) and Rieskamp et al. (2006) summarize standard context effects and the extant models that are, or are not, compatible with those effects holding. They do not discuss the recent *multiattribute linear ballistic accumulator (MLBA) model* (Trueblood et al., 2014) or the *2N-ary tree model* (Wollschläger and Diederich, 2012), to which we now turn.

Trueblood et al. (2014) show that their *context-dependent* MLBA model can produce various standard context effects in choice and various properties of the context effects when participants are under time pressure. These results are obtained by adding a context-dependent 'front end' to a context-independent LBA model. This suggests taking a fresh look at various choice-only models that can handle some or all such context effects in choice, and extending them to response time by, say, adding a context-independent LBA model that is driven by the 'front end' parameters of the choice model (see Marley and Regenwetter, in press).

The *2N-ary choice tree model* for N-alternative preferential choice (Wollschläger and Diederich, 2012) builds on earlier stochastic dynamic models (*accrual-halting models*, Townsend

et al., 2012) and thus includes details of the temporal accumulation of information. The structures, though not the details, of the 2*N*-ary choice tree model and of the context-dependent MLBA model are rather similar – the major differences are between the ballistic accumulators of the MLBA model and the transition probabilities of the 2*N*-ary choice tree model, and the fact that the MLBA model has no decay, whereas the 2*N*-ary choice tree model has decay. Each model well fits the data presented by its authors.

To date, the 2*N*-ary choice tree model has been applied to the best choice, though it includes a mechanism for rejecting options. Thus, it is of interest to extend the 2*N*-ary choice tree model to the best–worst choice and compare its fits to the data from such choice with those of the *parallel best–worst LBA model* (Hawkins et al., 2014).

Discussion and Conclusion

In contrast to the context-dependent MLBA model, the 2*N*-ary choice tree model and related stochastic dynamic models specify details of the temporal accumulation of information, rather than having a front end that incorporates the overall effect of such accumulated information. A significant part of the reason such stochastic dynamic models have not been used in applied areas is the "relatively high difficulty of estimating some sequential sampling models of decision making" (Berkowitsch et al., 2013). This difficulty is being alleviated, for example, by Berkowitsch et al.'s (2013) derivation of a tractable closed form for the choice probabilities given by an asymptotic form of decision field theory and by the various LBA models for (best, worst, best–worst) choice and response times.

The context-dependent models of choice and response time presented in this article involve numerous complex processes. Further empirical study along the lines of Teoderescu and Usher (2013), with follow-up theoretical work, is needed to clarify the conditions under which some or all these, and possibly other, processes are needed.

Nonetheless, the introduction of the notion of response (or decision) time into the random utility approach to modeling choice behavior has been very fruitful. It has brought about new insights into existing stochastic choice models and their characterizations, and it has generated new questions, many of which have only found partial answers up to now.

Decision and Choice: Sequential Decision Making

Adele Diederich, Jacobs University Bremen, Bremen, Germany

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Sequential decision making describes a situation where the decision maker makes successive observations of a process before a final decision is made. The procedure to decide when to stop taking observations and when to continue, the optimal stopping rule, depends on the specific assumptions made about the situation: the knowledge about the distribution of the observations, the distribution properties of the observations, whether the number of possible observations is bounded or unbounded, the sampling procedure, and the cost function for each observation. Many of these problems have been studied theoretically by mathematicians and experimentally by psychologists.

Sequential decision making describes a situation where the decision maker (DM) makes successive observations of a process before a final decision is made, in contrast to dynamic decision making (*see* Dynamic Decision Making), which is more concerned with controlling the system over time.

Formally, a sequential decision problem is such that the DM can take observations X_1, X_2, … one at a time. After each observation X_n, the DM can decide to terminate the process and make a final decision from a set of decisions D, or continue the process and take the next observation X_{n+1}. If the observations X_1, X_2, … form a random sample, the procedure is called sequential sampling.

In most sequential decision problems, there is an implicit or explicit cost associated with each observation. The procedure to decide when to stop taking observations and when to continue is called the stopping rule. The objective in sequential decision making is to find a stopping rule that optimizes the decision in terms of minimizing losses or maximizing gains including observation costs. The optimal stopping rule is also called the optimal strategy or the optimal policy.

A wide variety of sequential decision problems have been discussed in the statistics literature, including search problems, inventory problems, gambling problems, and secretary-type of problems, including sampling with and without recall. Several methods have been proposed to solve the optimization problem under specified conditions, including dynamic programing (*see* Dynamic Programing), Markov chains, and Bayesian analysis.

Sequential decision making plays an important role in applied research such as operations research, clinical research, computer science, economics, and political science with a variety of topics; for instance, clinical trials, structural learning, search algorithm, tutoring systems, marketing, portfolio, voting, and many more.

In the psychological literature, sequential decision problems are better known as optional stopping problems, optimal stopping problems, and sequential search problems. One line of research using sequential decision making is concerned with seeking information in situations such as buying houses, searching a job candidate, price searching, or target search. The DM continues taking observations until a decision criterion for acceptance is reached. Another line of research applies sequential decision making to account for information processing in binary choice tasks (*see* Diffusion and Random Walk Processes) and hypothesis testing such as in signal detecting tasks (*see* Signal Detection Theory). The DM continues taking observation until either one of two decision criteria is reached. Depending on the particular research area, observations are also called offers, options, items, applicants, information, and the like. Observation cost explicitly includes not only possibly money but also time, effort, aggravation, discomfort, and so on. Contrary to the objective of statisticians or economists, psychologists are less interested in determining the optimal stopping rule but are interested to find variables that affect human decision behavior on sequential decision tasks. Optimal decision strategies are considered as normative models and their predictions are compared to actual choice behavior.

Interestingly, research on sequential decision making with only one criterion received only moderate attention in psychology over the last decade or so, whereas research on sequential decision making with two criteria enjoy great popularity (*see* Diffusion and Random Walk Processes). The main focus here is on the former approach.

Sequential decision Making with One Decision Criterion

In sequential decision making with one decision criterion, the DM takes costly observations X_n, $n = 1, \ldots$ of a random process one at a time. After observing $X_n = x_n$, the DM has to decide whether to continue sampling observations or to stop. In the former case, the observation X_{n+1} is taken at a cost of c_{n+1}; in the latter case, the DM receives a net payoff that consists of the payoff minus the observation costs. The DM's objective is to find a stopping rule that maximizes the expected net payoff.

The optimal stopping rule depends on the specific assumptions made about the situation: (1) the distribution of X is known, not known, or partly known; (2) X_i are identically distributed for all i have the same distribution but with different parameters, or have different distributions; (3) the number of possible observations, n, is bounded or unbounded; (4) the sampling procedure, for example the option to take the highest value observed so far when stopping

 http://dx.doi.org/10.1016/B978-0-08-097086-8.43089-8

(sampling with recall) or only to take the last value when stopping (sampling without recall); and (5) the cost function, c_n, is fixed for each observation or is a function of n. Many of these problems have been studied theoretically by mathematicians and experimentally by psychologists. Pioneering experimental work was done in a series of papers by Rapoport and colleagues (1966, 1970, 1972).

Unknown Sample Distribution: Secretary-Type of Problems

Khan et al. (1967) investigated decision behavior in a sequential search task where the DM had to find the largest of a set of $n = 200$ numbers, observed one at a time from a deck of cards. The observations were taken in random order without replacement. The DM could only declare the current observation as the largest number (sampling without recall), and could compare the number with the previous presented numbers. No explicit cost for each observation were taken, that is $c = 0$. The sample distribution was unknown to the DM. A reward was paid only when the card with the highest number was selected, and nothing otherwise. The experiment describes a decision situation that is known as the secretary problem (a job candidate search problem; for various other names see, e.g., Freeman, 1983), which, in its simplest form, makes explicit the following assumptions (Ferguson, 1989):

1. Only one position is available.
2. The number n of applicants is finite and known.
3. The n applicants are interviewed sequentially in random order, each of the $n! = n\cdot(n-1)\cdot\cdots\cdot 2\cdot 1$ orders being equally likely.
4. All applicants can be ranked from best to worst without ties – the decision to reject or accept an applicant must be based only on the relative ranks of the applicants interviewed so far.
5. An applicant once rejected cannot later be recalled.
6. The payoff is 1 when choosing the best (i.e., the one with absolute rank 1) of the n applicants, 0 otherwise.

The optimal strategy for this kind of problems is to reject the first $s-1$, $s \geq 1$ items (cards, applicants, draws) and then to choose the first item that is best in the relative ranking so far. With

$$a_s \equiv \frac{1}{s} + \frac{1}{s+1} + \cdots + \frac{1}{n-1} \qquad [1]$$

the optimal strategy is to stop if $a_s < 1$ and to continue if $a_s > 1$, which can easily be determined for small n. For large n, the probability of choosing the best item is approximated by $1/e$ and the optimal s by n/e ($e = 2.71\ \ldots$). (For derivations, see, e.g., DeGroot, 1970; Freeman, 1983; Gilbert and Mosteller, 1966.)

Khan et al. (1967) found that about 40% of their participants did not follow the optimal strategy but stopped too late and rejected a card that should have been accepted. The failure of the strategy for describing behavior was assigned to its inadequacy for the described task. Although at the beginning of the experiment the participants did not know anything about the distribution (requirement), they could learn about the distribution by taking observations (partly information). To guarantee ignorance of the distribution, Gilbert and Mosteller (1966) recommended supplying only the rank of the observation made so far and not the actual value. Seale and Rapoport (1997) conducted an experiment following this advice. They found that participants stopped too early (with $n = 40$ and $n = 80$) than prescribed by the optimal stopping rule. They proposed simple decision rules or heuristics to describe choice behavior. Using a cutoff rule, the DM rejects the first $s-1$ applicants and then chooses the next top-ranked applicant, that is the candidate. The DM simply counts the number of applicants and the stops on the first candidate after observing $s-1$ applicants. Under a candidate count rule, the DM counts the number of candidates and chooses the jth candidate after observing $j-1$ candidates. A successive noncandidate rule requires the DM to choose the first candidate after observing at least k consecutive noncandidates following the last candidate. All three heuristics require minimal cognitive effort: merely counting applicants, candidates, or successive noncandidates is needed and comparing this number to some fixed parameter value. Seale and Rapoport (1997) results showed that the cutoff rule, which includes the optimal policy, accounted for the greatest proportion of choices.

The secretary problem has been extended and generalized in many different directions within the mathematical statistics field. Each of the above assumptions has been relaxed in one or the other way and optimal solutions were proposed (see Ferguson, 1989; Freeman, 1983, for reviews). Some of the generalizations have been tested empirically. For instance, Bearden and Rapoport (2005) described a so-called generalized secretary problem (GSP) in which the DM's objective is to find a good and not necessarily the best. The payoff function, 1 when selecting the best applicant and 0 otherwise, is replaced by a more general payoff function $\pi(a)$ for selecting an applicant with absolute rank a where $\pi(1) \geq \ldots \geq \pi(n)$. Experimental results showed that the DM stopped, on average, the search too early than predicted by the optimal decision rule (Bearden et al., 2006). Bearden et al. (2005) proposed a further generalization of the GSP to meet even more realistic decision situations. In the multiattribute secretary problem, the applicants differ along k different attributes. Within a given attribute, the applicants can be ranked from best (1) to worst (n) without ties. The attributes are correlated. The payoff function is $\pi^i(a^i)$, where a^i is the selected applicant's absolute rank on the ith attribute i and $\pi^1(1) \geq \ldots \geq \pi^i(n)$. Experimental results showed again that the DM examined fewer options, on average, than predicted by the optimal decision rule.

Known Sample Distribution

Rapoport and Tversky (1966, 1970) investigated choice behavior when the mean and the variance of the distribution were known to the DM. The cost for each observation was fixed but the amount varied across experimental conditions and the number of possible observations n was unbounded (1966) or bounded and known (1970). Behavior for sampling with and without recall was compared. When sampling is without recall, only the value of the last observation, $X_n = x_n$, can be received and the payoff is this value minus the total sampling cost, that is $x_n - cn$. The optimal strategy is to find a stopping

rule that maximizes the expected payoff $E(X_N - cN)$. When sampling is with recall, the highest value observed so far can be selected and the payoff is $\max(x_1, \ldots, x_n) - cn$ and the optimal strategy is to find a stopping rule that maximizes $E(\max(X_1, \ldots, X_N) - cN)$. In the following, v with subscripts and v^* denote the expected gain from an (optimal) procedure.

Number of Observations Unbounded

If n is unbounded, that is if the number of observations that can be taken is unlimited, and $X_1, X_2, \ldots$ are sampled from a known distribution function $F(x)$, the optimal strategy is the same for both sampling with and without recall. In particular, the optimal strategy is to continue to take observations whenever an observed value $x_j < v^*$ and to stop taking observations as soon as an observed value $x_j \geq v^*$, where v^* is the unique solution of

$$\int_{v^*}^{\infty} (x - v^*)\mathrm{d}F(x) = c \qquad -\infty < v^* < \infty. \qquad [2]$$

When the observations are taken from a standard normal distribution with density functions $\phi(x)$ and distribution function $\Phi(x)$, one has that

$$v^* = \frac{\phi(v^*) - c}{1 - \Phi(v^*)}. \qquad [3]$$

Although sampling with and without recall has the same solution, they seem to be different from a psychological point of view. Rapoport and Tversky (1966) found that the group sampling without recall took significantly fewer observations than the participants sampling with recall. The mean number of observations for both groups decreased with increasing cost c, and the difference with respect to the number of observations taken was diminished. However, the participants of both groups took fewer observations than prescribed by the optimal strategy. This nonoptimal behavior of the participants was attributed to a lack of thorough knowledge of the distributions.

Number of Observations Bounded

If $n, (n \geq 2)$ is bounded, that is, if not more than n observations can be taken, the optimal stopping rules for sampling with and without recall are different. For sampling without recall, an optimal procedure is to continue taking observations whenever $x_j < v_{n-j} - c$ and to stop as soon as $x_j \geq v_{n-1} - c$, where $j = 1,2, \ldots, n$ indicates the number of observations that remain available and

$$v_{j+1} = (v_j - c) - \int_{v_j - c}^{\infty} (x - (v_j - c))\mathrm{d}F(x). \qquad [4]$$

With $v_1 = E(X) - c$, the sequence can be computed successively. Again, assuming a standard normal distribution $v_{j+1} = \phi(v_j - c) + \Phi(v_j - c)$.

For sampling with recall, the optimal strategy is to continue the process whenever a value $x_j < v^*$ and to stop taking observations as soon as an observed value $x_j \geq v^*$, where v^* is as in eqn [2], which is the same as for n unbounded. (For derivations of the strategies, see DeGroot, 1970; Sakaguchi, 1961.)

Rapoport and Tversky (1970) investigated choice behavior within this scenario. Sampling was done with and without recall. The number of observations that could be taken as well as observation cost varied across experimental groups. One-third of the participants did not follow the optimal strategy. Under both sampling procedures and all cost conditions, they took on average fewer observations than predicted by the corresponding optimal stopping rules. There were no systematic differences due to cost as observed in their previous study. They concluded that "the optimal model provides a reasonable good account of the behavior of the subjects" (p. 119).

Different Sample Distributions for Each Observation

Most research concerned with sequential decision making assumes that the observations are sampled from the same distribution; that is X_i are identically distributed for all i. For many decision situations, however, the observations may be sampled from the same distribution family with different parameters, or from different distributions. Especially in economical areas, such as price search, it is reasonable to assume that the distributions from which observations are taken change over time. The sequence of those samples has been called nonstationary series. Of particular interest are two special nonstationary series: ascending and descending series. For ascending series, the observations are drawn from distributions, usually from normal distributions, with increasing mean as i increases; for descending series the mean of the distribution decreases as i increases, i indicating the sample index. For both cases, experiments have been conducted to investigate choice behavior in a changing environment. Shapira and Venezia (1981) compared choice behavior for ascending, descending, and constant (identically distributed X_i) series. In one experiment (numbers from a deck of cards), the distributions were known to the DM; no explicit observation cost were taken; sampling occurred without recall; and the number of observations that could be taken was limited to $n = 7$. The variance of the distributions varied across experimental groups. An optimal procedure was assumed to continue taking observations whenever $x_j < v_{n-j}$ and to stop as soon as $x_j \geq v_{n-1}$, where $j = 1,2, \ldots, n$ indicates the number of observations that remain available. $k = 1, \ldots, n$ indicates the specific distribution for the jth observation. Thus,

$$v_{j+1} = v_j - \int_{v_j}^{\infty} (x - v_j)\mathrm{d}F_k(x). \qquad [5]$$

With $v_1 = E(X_1)$, the sequence can be computed successively. Assuming a standard normal distribution $v_{j+1} = \phi_k(v_j) + \Phi_k(v_j)$.

Across all conditions, 58% of the participants behaved in an optimal way. The proportion of optimal stopping did not depend on the type of the series but depended on the size of the variance. Nonoptimal stopping (24% stopped too early; 18% too late) depended on the series and on the size of the variance. In particular, participants stopped too early on ascending and too late on descending series. A similar result was observed by Brickman (1972). In that study, departing from the optimal stopping rule was attributed to an inadequacy of the

stopping rule taken for the particular experimental conditions (assuming complete knowledge of the distributions). In a secretary problem design (*see* Unknown Sample Distribution: Secretary-Type of Problems), Corbin et al. (1975) were less concerned with optimal choice behavior than with the processes by which the participants made their selections, and with factors that influenced those processes. The emphasis of the investigation was on decision-making heuristics rather than on the adequacy of optimal models. With the same optimal stopping rule for all experimental conditions, they found that stopping behavior depended on contextual variables such as the ascending or descending trend of the inspected numbers of the stack.

In summary, Eriksson and Strimling (2010) argue that suboptimal search behavior is to be expected because optimal strategies differ greatly with subtle details of the search problem setup. People, however, seem to hold general intuitions about the optimal amount of search to be conducted before stopping. Generally, they are not able to foresee how the optimal amount of search depends on details of the problem and therefore, they will be incorrect for most problems.

Search Problems – Multiple Information Sources

In a sequential decision-making task with multiple information sources, the DM has the option to take information sequentially from different sources. Each information source may provide valid information with a particular probability and at different cost. The tasks are to decide not only to stop or to continue the process but also, if continuing, which source of information to consult.

Early experimental studies have been done by Kanarick et al. (1969), Rapoport (1969), and Rapoport and Wallsten (1972). A typical task is to find an object (e.g., a black ball) that is hidden in one of several possible locations (e.g., in one of several bins containing white balls). The optimal search strategy depends on further task specifications, such as whether the object can move from one location to another, how many objects are to be found, and whether the search process may stop before the object has been found. Rapoport (1969) investigated the case when one single object that could not move was to be found in one of r, $r \geq 2$ possible locations. The DM was not allowed to stop the process before the target was found. All of the following were known to the DM: the priori probability p_i, $p_i > 0$ that the object is in location i, $i = 1,2, \ldots, r$ with $\sum_{i=1}^{r} p_i = 1$; miss probability α_i, $0 < \alpha_i < 1$, that even if the object is in location i it will not be found in a particular search of that location ($1 - \alpha_i$ is referred to the respective detection probability); and a cost, c_i, for a single observation at location i. The objective of the DM is to find a search strategy that minimizes the expected cost. For $i = 1, \ldots, r$ and $j = 1,2, \ldots$, let Π_{ij} denotes the probability that the object is found at location i during the jth search and the search is terminated. Then,

$$\Pi_{ij} = p_i \alpha_i^{j-1}(1 - \alpha_i), \quad i = 1, \ldots, r, \quad j = 1, 2, \ldots \qquad [6]$$

If all values of Π_{ij}/c_i for all values of i and j are arranged in order of decreasing magnitude, the optimal strategy is to search according to this ordering (for derivations, see DeGroot, 1970). Ties may be arbitrarily ordered among themselves. The optimal strategy is determined by the detection probabilities and observation costs, and optimal search behavior implies a balance between maximizing the detection and minimizing the observation cost. Rapoport (1969) found that participants did not behave optimally. They were more concerned with maximizing the probability of detecting the target than with minimizing observation cost. Increasing the difference of observation cost c_i among the $i = 1, 2, 3, 4$ locations showed that the deviation from the optimal strategy even increased. Rapoport and Wallsten (1972) varied the search problems by allowing the DM to terminate the search any time; adding a terminal reward, R, for finding the target; and a terminal penalty, B, for not finding the target. Most participants showed a bias toward maximizing detection probability versus minimizing search cost per observation, similar to the previous study.

Sequential Decision Making with Two Decision Criteria

A random sample $X_1, X_2, \ldots$ is generated by an unknown value θ of state of the world, or unknown state of nature, Θ. The DM can take observations one at a time. After observing $X_n = x_n$, the DM makes inferences about Θ based on the values of $X_1, \ldots, X_n$ and can decide whether to continue sampling observations or to stop the process. In the former case, observation X_{n+1} is taken; in the latter case, the DM makes a final decision $d \in D$. The consequences to the DM depend on the decision d and the value θ.

The statistical theory for this situation has been developed by Wald during the 1940s. It has been used to test hypotheses and estimate parameters. In the psychology research, sequential decision making of this kind is usually limited to two decisions $D = \{d_1, d_2\}$ and applied to binary choice tasks (*see* Diffusion and Random Walk Processes; Bayesian Theory, History, Applications, and Contemporary Directions).

The standard theory of sequential analysis by Wald (1947) does not consider observation costs $C(n)$, losses for terminal decisions $L(\theta, d)$, and a priori (subjective) probabilities π about the state of nature as variables. Deferred decision theory generalizes the original theory by including these variables explicitly. The objective of the DM is to find a stopping rule that minimizes expected loss (called risk) and expected observation cost. The form of that optimal stopping rule depends mainly on the assumption about the number of observations that can be taken (bounded or unbounded) and on the assumption of cost per observation (fixed or not) (see DeGroot, 1970). Birdsall and Roberts (1965), Edwards (1965), and Rapoport and Burkheimer (1971) introduced the idea of deferred decision theory as normative models of choice behavior to the psychological community. Experiments investigating human behavior in deferred decision tasks were done by Pitz and colleagues in a series of papers (e.g., 1969) and by Busemeyer and Rapoport (1988). Rapoport and Wallsten (1972) summarize experimental findings.

For illustration, assume the decision problem in its simplest form. Suppose two possible states of nature θ_1 and θ_2 and two

possible decisions d_1 and d_2. Cost c per observation is fixed and the number of observations is unbounded. The DM does not know which of the states of nature, θ_1 or θ_2, is generating the observation but there are a priori probabilities π that it is θ_1 and $(1-\pi)$ that it is θ_2. Let w_i denote the loss for a terminal decision incurred by the DM in deciding that θ_i is not the correct state of nature when it actually is $(i = 1, 2)$. No losses are assumed when the DM makes a correct decision. Let π_n denote the posterior probability that θ_1 is the correct state of nature generating the observations after n observations have been made. The total posterior expected loss is $r_n = \min\{w_1\pi_n, w_2(1-\pi_n)\} + nc$. The DM's objective is to minimize the expected loss. An optimal stopping rule is specified in terms of decision boundaries, α and β. If the posterior probability is greater than or equal to α, then decision d_1 is made; if the posterior probability is smaller than or equal to β, then d_2 is selected; otherwise sampling continues.

Decision Making: Nonrational Theories

Abstract

In a world of known risks, rational theories provide the norms for successful behavior. In a world where not all risks are known and where optimization is not feasible, 'nonrational' tools such as heuristics are needed. In comparison to optimization models, heuristics are robust and can lead to more accurate predictions, while saving time and effort. The study of heuristics addresses the descriptive question of what heuristics an individual or institution has in their 'adaptive toolbox,' as well as the normative question of their ecological rationality, i.e., which heuristics in which situations are most accurate and effective.

Nonrational theories are not theories of irrationality. Rather, they dispense with unrealistic assumptions such as omniscience and optimization in the so-called rational theories. Most important, nonrational theories apply to 'decision-making under uncertainty,' where not all alternatives, consequences, and probabilities are known or knowable (e.g., whom to marry? what job to take? where to invest?). Rational theories, in contrast, are tailored to situations where all risks are known, as in lotteries and roulette ('decision-making under risk'), and where the optimal choice can be calculated. The majority of important problems lie between the two poles of risk and uncertainty, which indicate the necessity of considering both approaches.

Nonrational theories have been denoted by various terms, including *models of bounded rationality*, *procedural rationality*, *fast-and-frugal heuristics*, and *satisficing*. Although there is as yet no consensus on the definition of *nonrational*, these theories typically differ from rational theories on several dimensions, discussed below. The term *decision-making* is used broadly here to include both conscious and unconscious preference, inference, classification, and judgment.

As mentioned, the label *nonrational* should not be confused with irrational behavior: It signifies a type of process, not a type of outcome. In other words, the fact that nonrational theories postulate agents with emotions, limited knowledge, and little time – rather than omniscient 'rational' beings – need not imply that such agents fare badly in the real, uncertain world. We will focus on the theory of heuristics, which is probably the best developed among nonrational theories that do not rely on optimization (Gigerenzer et al., 2011).

Historical Background

A few historical remarks on rational theories help to set the stage. In the mid-seventeenth century, the calculus of probability replaced the ideals of certain knowledge and demonstrative proof (as in mathematics and religion) with a more modest vision of reasonableness. What may be called the first rational theory of decision-making, the maximization of expected value, emerged at this time. According to the theory, an option's expected value is the sum of the product of the probability and the value of each of its consequences; a rational decision-maker chooses the option with the highest expected value.

The notion of defining an option's reasonableness in terms of its expected value soon ran into problems because its prescriptions conflicted in some situations (e.g., the St Petersburg problem) with educated intuition. Daniel Bernoulli therefore proposed replacing the concept of expected value with that of expected utility. For instance, the utility of a monetary gain (say, of $1000) can be defined as a logarithmic function of its dollar value and the agent's current wealth, assuming that the utility of an additional dollar diminishes as the value of the gain and current wealth increase.

The fact that rational decision-making can be defined in more than one way – for example, as maximization of expected value or expected utility – has been interpreted both as the weakness and strength of the program. This ambiguity was one of the reasons why, by 1840, most mathematicians had given up attempting to define a calculus of reasonableness (Daston, 1988). With a few exceptions, rational theories of decision-making largely disappeared until their revival in the 1950s and 1960s. Only then did the major types of rational theories, the maximization of subjective expected utility and Bayesianism, become influential in the social and behavioral sciences. At about the same time, some psychologists and economists – most notably Nobel laureates Herbert Simon and Reinhard Selten – criticized the assumptions about the human decision-maker in modern rational theories as empirically unfounded and psychologically unrealistic, calling for alternative theories.

Optimizing versus Nonoptimizing Theories

Rational theories rest on the ideal of optimization. Optimization entails the calculation of the maximum (or minimum) of some variable across a number of alternatives or values. Nonrational theories, by contrast, apply in the situations where optimization is not feasible. In many real-world situations, no optimizing strategy is known. Even in a game such as chess, whose few rules are stable and well-defined, the optimal strategy (which in fact exists) cannot be computed by a human

or a machine. And even when an optimizing strategy can be calculated, it may demand unrealistic amounts of knowledge about alternatives and consequences, particularly when the problem is novel and time is scarce. Acquiring the requisite knowledge can conflict with goals such as making a decision quickly; in situations of immediate danger, attempting to optimize can actually be deadly. In social and political situations, making a decision at all can take priority over searching for the best option. Most important, for decisions made under uncertainty (i.e., most of our decisions), strategies that do not attempt to optimize (heuristics) can outperform strategies that do. In other words, the concept of an optimizing strategy needs to be distinguished from the concept of an optimal outcome. In an uncertain world, there is no guarantee that 'optimization' will result in a good or optimal outcome. An example is the problem of allocating money to N funds. While Markowitz's Nobel prize-winning mean–variance portfolio is optimal under the assumptions made, in the real world of investment a simple heuristic, 1/N ("allocate your money equally to N assets"), can lead to better performance (DeMiguel et al., 2009).

Normative versus Descriptive Theories

Nonrational theories are descriptive, whereas rational theories are normative – this common distinction is only partly true. Indeed, theories of heuristics are concerned with psychological realism, that is, the capacities and limitations of actual humans, whereas rational theories have little concern for descriptive validity and tend to assume omniscience. But theories of heuristics are normative as well. For instance, in situations where an optimization strategy is nonexistent, unknown, or dangerous because it would impede decision-making, a simple heuristic – such as imitating the behavior of others – can be the better strategy.

Rational theories typically do not assume that agents actually perform optimization or have the knowledge needed to do so. Their purpose is not to describe the reasoning process, but to answer a normative question: What would be the best strategy for an omniscient being to adopt? In economics, psychology, and animal behavior, however, the answer to this question is sometimes used to predict actual behavior. In this way, a rational theory can be descriptive of behavioral outcomes, yet be mute about underlying processes. For instance, optimal foraging theory assumes that animals select and shift between food patches *as if* they had perfect knowledge about the distribution of food, competitors, and other relevant information, without claiming that real animals have this knowledge or perform optimizing computations. Instead, it is assumed that animal behavior has evolved to be close to optimal in specific environments. The question of what proximal mechanisms produce this behavior is a different one. These mechanisms may be simple heuristics such as 1/N and social imitation; that is, the topic of theories of nonrational decision-making.

Ecological Rationality versus Internal Consistency

A classical criterion for rational choice is internal consistency or coherence. Numerous rules of consistency have been formulated: for instance, transitivity and additivity of probabilities. Beginning with in the work of Jean Piaget and Bärbel Inhelder, these rules, which are the building blocks of rational theories, have been used to investigate the development of human thinking. Theories of heuristics, in contrast, place less weight on internal consistency; some heuristics, for instance, can violate transitivity. Instead, their emphasis is on performance in the external world, both physical and social. Measures of external performance include the accuracy, speed, frugality, transparency, and accountability of decision-making. Note that internal consistency does not guarantee that any of these external criteria are met. For instance, although the statement 'there is a 0.01 probability that cigarette smoking causes lung cancer and a 0.99 probability that it does not' is internally consistent in that the probabilities add up to 1, according to relevant research, it is not accurate.

The study of the ecological rationality of heuristics, or strategies in general, is a framework to study performance in the external world: A heuristic is ecologically rational to the degree that it is adapted to the structure of the environment. Heuristics are 'domain-specific' rather than 'domain-general'; that is, they work in a class of environments in which they are ecologically rational. Heuristics provide not a universal rational calculus but a set of domain-specific mechanisms similar to the parts of a Swiss army knife, and have been referred to collectively as the 'adaptive toolbox' (Gigerenzer and Selten, 2001). Thus, the important research question is to specify, for a given heuristic, the structures of environments in which it is faster or more accurate than other strategies in achieving a goal.

For instance, the 1/N heuristic is likely to lead to better returns than the mean–variance portfolio when (1) uncertainty is high (as in the real stock market), (2) sample size is small (typically not more than 10 years of data used by banks), and (3) N is large (because estimation error increases with N). The study of ecological rationality fleshes out Simon's scissors analogy: "Human rational behavior (and the rational behavior of all physical symbol systems) is shaped by a scissors whose two blades are the structure of task environments and the computational capabilities of the actor" (Simon, 1990: p. 7). By looking at only one blade, cognition, it is impossible to understand why and when a behavior succeeds or fails.

Structures of Environments

While some optimization theories treat decision-making as if there were only one tool – maximization of expected utility – the study of decision-making under uncertainty shows that people rely on several tools, not just one. Simple heuristics can succeed by exploiting the structure of information in an environment. In other words, the environment itself can do part of the work for the heuristic. Environmental structures that have been identified to be important in determining the success of heuristics in comparison to other strategies include:

1. Uncertainty: how well a criterion can be predicted.
2. Sample size: number of observations (relative to number of cues).
3. Number of alternatives (N).
4. Redundancy: the correlation between cues.
5. Variability in weights: the distribution of the cue weights (e.g., skewed or uniform).

For instance, heuristics that rely on only one reason, such as *take-the-best* (see below), tend to make more accurate predictions than do strategies such as linear regression in environments with (1) moderate to high uncertainty and (2) moderate to high redundancy. The study of ecological rationality results in comparative statements of the kind "strategy X is more accurate (frugal, fast) than Y in environment E," or in quantitative relations between the performances of strategy X when the structure of an environment changes. Specific findings are introduced in Section Classes of Heuristics.

The concept of ecological rationality should not be confused with the biological concept of adaptation: A match between a heuristic and an environmental structure does not imply that the heuristic evolved because of that environment. Nor does ecological rationality mean that the mental representation mirrors the world: A heuristic is functional, not a veridical copy of the world.

Robustness

A second reason why a simple heuristic can make accurate predictions is robustness. To understand this point, it is necessary to distinguish between data fitting (i.e., determining the best-fitting parameter values for a model given a specific body of data) and prediction (i.e., using these parameter values to predict new data). For data fitting, it generally holds that the more parameters a model has, the better the fit, whereas for prediction there can be a point where less is more. For instance, when recording the air temperature on all 365 days of a year, one can fit the resulting jagged curve increasingly well by adding more free parameters to the model. However, for predicting the daily temperature in the year thereafter, the model that best fits the past data may be less accurate in predicting than a simpler model with fewer parameters and a worse fit. More generally, in noisy environments only part of the available information generalizes to the future. The art of building a good model is to find this part and to ignore the rest. The more noise in the environment, the more models with many free parameters tend to overfit, that is, reflect the noise in a specific sample. Overfitting can become a problem when overly powerful mathematical models, such as neural networks with numerous hidden units and multiple regression with many predictors, are used to fit and then predict behavioral data. Simplicity can reduce overfitting and thereby produce robust decision strategies. A general formulation for when and why one should simplify is the bias–variance dilemma (Geman et al., 1992).

In much research on reasoning, a *bias* typically refers to ignoring part of the information, as in the base-rate fallacy. This can be captured by the equation:

$$\text{Error} = \text{bias} + \varepsilon \qquad [1]$$

where ε is an irreducible random error. In this view, if the bias is eliminated, good inferences are obtained. In statistical theory, however, there are three sources of errors:

$$\text{Error} = \text{bias}^2 + \text{variance} + \varepsilon \qquad [2]$$

where *bias* refers to a systematic deviation between a model and the true state, as in eqn [1]. To define the meaning of *variance*, consider 100 people who rely on the same strategy but have different samples of observations from the same population. Because of sampling error, the 100 predictions may not be the same. Across samples, variance is the expected squared deviation around their mean, while bias is the difference between the mean prediction and the true state of nature.

Consider the problem many companies face in predicting which of their thousands of customers will continue to be active, that is, make purchases in the future. To do so, the Pareto/negative binomial distribution (NBD) model relies on complicated math to estimate its four free parameters from previous data. In contrast, the hiatus heuristic used by experienced managers classifies customers as active only if they have made a purchase within the last 9 months (the hiatus). It was shown to predict customer purchases more accurately than the Pareto/NBD model, despite using less information (Wübben and von Wangenheim, 2008). The bias–variance dilemma provides an explanation for this less-is-more effect. Because the hiatus heuristic does not need to estimate any parameters, it has zero variance, although it probably has a strong bias. In contrast, the Pareto/NBD model likely has a smaller bias but, nevertheless, a larger overall error because it additionally suffers from variance.

Variance decreases with increasing sample size, but also with simpler strategies that have fewer free parameters (and less flexible functional forms; Pitt et al., 2002). Thus, a cognitive system needs to draw a balance between being biased and flexible (variance), rather than simply trying to eliminate bias. Heuristics can be fast, frugal, and accurate by exploiting the structure of information in environments, by being robust, and by striking a good balance between bias and variance. This bias–variance dilemma helps to understand the rationality of simple heuristics and why less can be more (Brighton and Gigerenzer, 2008).

Classes of Heuristics

A heuristic is a strategy that ignores part of the information, with the goal of making decisions more accurately, quickly, and frugally (i.e., with fewer pieces of information) compared to more complex methods. Heuristics are defined by common *building blocks* from which the various heuristics are constructed as an organizing principle. This allows the larger number of heuristics to be reduced to a smaller number of components, similar to how the chemical elements in the periodic table are built from a small number of particles. Three building blocks have been proposed:

1. *Search rules* specify in what direction search extends in the search space.
2. *Stopping rules* specify when search is stopped.
3. *Decision rules* specify how the final decision is reached.

Different classes of heuristics have been specified, all of which can be described in terms of these building blocks. Fast-and-frugal heuristics model decision-making as a dynamic process in which cues or reasons are sequentially searched for – in memory or in the outside world – and inferences are determined by simple stopping and decision rules. The challenge is to understand what the class of heuristics is, how

a heuristic is selected, and in which environments it is successful. The following summary is based on Gigerenzer and Gaissmaier (2011), where further references can be found.

Recognition-Based Decision-Making

The recognition memory literature indicates that a sense of recognition (often called *familiarity*) appears more quickly than recollection in consciousness. This core capacity is exploited by the first class of heuristics. The goal is to make inferences about a criterion that is not directly accessible to the decision-maker, based on recognition retrieved from memory. Prominent heuristics in this class are the recognition heuristic and the fluency heuristic.

Recognition Heuristic

If one of two alternatives is recognized and the other is not, infer that the recognized alternative has the higher value with respect to the criterion (Goldstein and Gigerenzer, 2002). This heuristic is ecologically rational in an environment (reference class) R to the degree the recognition of alternatives a, b ∈ R positively correlates with their criterion value. If the correlation between recognition and the criterion is sufficiently large, a counterintuitive result is observed: Knowing fewer alternatives can lead to more accurate predictions than knowing more alternatives because people who recognize both alternatives cannot use the heuristic.

The recognition heuristic is a model that relies on recognition only and assumes that people will ignore strong, contradicting cues (the so-called noncompensatory inferences). Much research in the past decade was devoted to investigating to what degree people actually rely on the recognition heuristic in such a noncompensatory fashion, and what the boundary conditions are. Additionally, research has identified several environments in which, from a prescriptive perspective, the recognition heuristic is ecologically rational and can compete with well-established forecasting instruments. These environments include the prediction of sports results such as Wimbledon or soccer, election outcomes, university rankings, and geographical properties such as the size of cities or mountains (for a recent overview of the discussion, see Marewski et al., 2011).

Fluency Heuristic

If both alternatives are recognized but one is recognized faster, then infer that this alternative has the higher value with respect to the criterion (Schooler and Hertwig, 2005).

The fluency heuristic is ecologically rational if the speed of recognition is correlated with the criterion, that is, the fluency validity >0.5. Fluency has been shown to predict the performance of stocks, sales figures, and wealth. The validity of fluency is typically lower than that of recognition, but above chance. Fluency also plays a role when alternatives are not given (as in two-alternative choice) but need to be generated from memory. Johnson and Raab (2003) showed, for instance, that experienced handball players can successfully rely on the first alternative that comes to mind when deciding which move to make in a game (a strategy they called *take-the-first*).

One-Reason Decision-Making

While the recognition and fluency heuristics base decisions on recognition information, other heuristics rely on recall. One class looks for only one 'clever' cue and bases its decision on that cue alone, as in the hiatus heuristic (see above). A second class involves sequential search through a number of cues but also bases its decision on just one. Examples include lexicographic rules and elimination-by-aspect (Tversky, 1972). These heuristics were originally developed for preferences; here, the focus is on models of inferences.

One-Clever-Cue Heuristics

What this class of heuristics has in common is that a decision is based on one specific cue only. Many animal species appear to rely on one cue for locating food, nest sites, or mates. For instance, to catch a fly ball high in the air, baseball players rely on the gaze heuristic *"fixate your eye on the ball, start running, and adjust the running speed so that the angle of gaze remains constant."* Variants of this heuristic that rely only on the optical angle have been observed in bats, birds, and fish when pursuing a prey or a mate. Similarly, to choose a mate, peahens have been reported to investigate only three or four of the peacocks displaying in a lek and choose the one with the largest number of eyespots (Petrie and Halliday, 1994). The ecological rationality of one-clever-cue heuristics is not entirely clear at this point in time, but candidates are environments where the variability of cue weights and redundancy is moderate to high and sample size is small (Hogarth and Karelaia, 2007).

Take-the-Best Heuristic

This heuristic is a model of how to infer which of two alternatives has a higher value on a criterion, based on binary cue values retrieved from memory: *Search through cues by their validities, and stop search when the first cue is found that allows for a decision.* A striking discovery was that take-the-best's predictions can be more accurate than those of linear multiple regression models (Czerlinski et al., 1999) and complex nonlinear strategies such as an exemplar-based model (nearest-neighbor classifier), Quinlan's decision-tree induction algorithm C4.5, and classification and regression trees (CART) (Brighton and Gigerenzer, 2008). Research on the ecological rationality of take-the-best suggests two structures of environments it can exploit: moderate to high cue redundancy and moderate to high variability in cue weights (Hogarth and Karelaia, 2007). And it is precisely these features that determine when people's inferences can best be predicted by take-the-best and when they cannot, indicating adaptive strategy use (Bröder, 2012). Variants of take-the-best have been successfully applied to model consumer choice and improve literature search.

Fast-and-Frugal Trees

One way to model classification is in terms of trees. For instance, for m binary cues or attributes, Bayes' rule can be represented as a tree with 2^m leaves. In contrast, a fast-and-frugal tree is defined as a tree with $m + 1$ exits only, with exits at each cue: *Search sequentially through cues, and stop search as soon as a cue leads to an exit* (Martignon et al., 2003). When the number of cues grows, a Bayesian tree becomes computationally intractable or fraught with estimation error because one

typically has too few data points for the thousands of 'leaves' of such a gigantic tree. In contrast, a fast-and-frugal tree needs to estimate fewer parameters and is likely more robust. Fast-and-frugal trees are used by experts in many fields, from emergency medicine to bail decisions.

Trade-off Heuristics

Unlike recognition-based and one-reason decisions, the third class of heuristics weights cues or alternatives equally and thus makes trade-offs (compensatory strategies).

Tallying

Whereas take-the-best ignores cues (but includes a simple form of weighting cues by ordering them), tallying ignores weights and simply counts the number of cues favoring one alternative to others. Dawes (1979) showed that tallying was about as accurate as multiple regression in its predictions and sometimes even better. In a more extensive test across 20 environments, Czerlinski et al. (1999) demonstrated that tallying had, on average, a higher predictive accuracy. The challenge is to figure out *when* this is the case. Einhorn and Hogarth (1975) found that unit-weight models were more successful than multiple regression when the ratio of alternatives to cues was 10 or smaller, the linear predictability of the criterion was small ($R^2 \leq 0.5$), and cues were highly redundant. Successful applications of variants of tallying include predicting strokes with simple bedside rules (which actually outperformed magnetic resonance imaging (MRI) in this regard) and avoiding avalanches.

Mapping Model

How do people arrive at quantitative estimates based on cues? The mapping model assumes that people tally the number of relevant cues with an object's positive values (von Helversen and Rieskamp, 2008). The estimate is the median criterion value of objects with the same number of positive cues. People's judgments were better captured by this model than by a linear regression and an exemplar model when the criterion values followed a skewed distribution, and it was successfully applied to predict sentencing decisions.

1/N Heuristic

Another variant of the equal weighting principle is the 1/N heuristic (also known as the *equality heuristic*), which is a simple rule for the allocation of resources (time, money) to N alternatives. Use of this heuristic has been reported for financial investment (see above), parental investment, and as a tool for fair allocation of money in experimental games.

Aspiration Level Theories

Simon (e.g., 1956, 1982) proposed a heuristic known as *satisficing*, which allows an agent to make a decision without evaluating or even knowing all the alternatives: *Set an aspiration level, search through alternatives sequentially, and stop search as soon as an alternative is found that satisfies the level.* An aspiration level is either a value on a goal variable (e.g., profit or market share) or, in the case of multiple goals, a vector of goal values that is satisfactory to the agent. For instance, agents might set a lower limit on the price at which they would be willing to sell their shares in a company (the aspiration level). In this satisficing model, the agent makes no attempt to calculate an optimal stopping point (here, the best day on which to sell). The aspiration level need not be fixed but can be dynamically adjusted to feedback. For instance, if the investors observe that the share price is monotonically increasing rather than fluctuating over time, they might conclude that there is some stable trend and adjust the limit upward. Thus, aspiration level theories model decision-making as a dynamic process in which alternatives are encountered sequentially and aspiration levels stop search. The challenge is to understand where aspiration levels come from in the first place (Selten, 1998; Simon, 1982).

Summary

In a world of known risks, rational theories provide the norms for successful behavior. In a world where not all risks are known, statistics and logic are not sufficient – additional tools, such as heuristics, are needed. Although heuristics are often classified as nonrational, there is nothing irrational about them. The study of the adaptive toolbox analyzes the heuristics that an individual, a profession, or society relies on to deal with an uncertain world. While this analysis is descriptive, the study of the ecological rationality addresses the normative questions of what heuristic to rely on in what situation. The emerging science of heuristics shows when and why complex problems do not need complex solutions, and why less information can be more.

Abstract

The psychology of decision making combines concepts, models, and methods from a variety of disciplines. It describes and explains the discrepancies between normative models of decision making and actual behavior. It also highlights the adaptive nature of human decision making, the use of heuristics, and simple decision rules that can improve our decision making but can also have detrimental effects on the quality of our judgment. The interplay between affect and cognition is also studied in this tradition, and this has improved our insight in both intuitive and more deliberate decision making.

Human decision making has been studied by a variety of disciplines including economics, philosophy, psychology, biology, and statistics. Behavioral decision making or judgment and decision making (JDM), as the field is generally known in psychology, is being studied in all branches of psychology. The starting point of much work on human JDM is rational choice theory. The most influential explanatory concept in the analysis of decisions under uncertainty is the subjective expected utility (SEU) of available alternatives. SEU theory is a normative theory and is often compared to actual decisions. Deviations that violate the rational principles underlying SEU theory systematically are termed anomalies. Anomalies of decision making will be briefly discussed in this section, followed by descriptive theories of decision making including work on heuristics. Next we turn to a comparison of intuitive versus deliberate decision modes and also pay attention to the role of affect and emotions in decision making.

Normative Theories of Decision Making

Traditionally, choices are assumed to be consequential, and options are evaluated using prior assessments of beliefs and values. Generally, research in this field of research focuses on a *probability* component or a *value* component, or both.

Edwards (1954) provided the first major review of research on human JDM. He argued that normative and prescriptive models based on economic and statistical theory should also be relevant to psychologists interested in human JDM. Edwards introduced SEU theory, which decomposes decisions or choices in probabilities and preferences, and provides a set of rules for combining beliefs (probabilities) and preferences ('values' or 'utilities'). (Decomposes decisions in beliefs (probabilities) and preferences (values or utilities) that are combined to assess the overall utility of an outcome.) Utility maximization is considered an appropriate normative rule for decision making under risk or uncertainty. The theory is normative or prescriptive because it specifies how decisions *should* be made. If one accepts the axioms upon which it is based, then the most rational choice or decision is the one specified by the theory as having the highest expected utility.

The axioms of SEU theory are all based on the work of Von Neumann and Morgenstern. Their work showed that if a person's choices follow certain rules or axioms, it is possible to derive utilities in such a way that a preference for a specific alternative implies that its expected utility is greater than that of the other alternative(s). Their approach assumes that it is possible to associate a real number with each possible consequence of the relevant alternatives. This number (e.g., a number between 1 and 10) represents the utility of that consequence for the individual. The *expected utility* of a specific alternative is then the sum of the numbers associated with each possible consequence weighted by the probability that each consequence will occur. Thus a positive or negative outcome will be weighted by the probability of its occurrence; for example, a certain outcome will be multiplied by 1.0, an outcome with a probability of 0.5 will be multiplied by 0.5, etc.

To illustrate this let us compare the two jobs in terms of three possible outcomes or consequences. These are initial salary, career opportunities, and atmosphere. Initial salary is higher at firm A than at firm B, and receives ratings of 8 and 7, respectively, on a scale ranging from 1 to 10. Career opportunities seem better at firm B, but this element cannot be assessed with certainty. Let us assume that career opportunities get ratings of 8 (firm A) and 9 (firm B), but that you are less certain of your assessment of firm A (subjective probability of 0.7) than of firm B (subjective probability of 0.9). Finally, the atmosphere at firm B seemed to be better than at firm A; your scores are 8 and 7, respectively. You spent quite some time at firm B and are certain about your judgment of the atmosphere (it seemed a great team of colleagues). You are less certain about your verdict of the atmosphere at firm A because you spent less time there (probabilities of 1.0 (B) vs 0.9 (A)). This leads to the following scores: Firm A ($1.0 \times 8 + 0.7 \times 8 + 0.8 \times 7 = 20.0$), Firm B ($1.0 \times 7 + 0.9 \times 9 + 1.0 \times 8 = 23.2$). Thus, according to this analysis, the job offer of firm B is more attractive than that of firm A.

The central idea of the Von Neumann and Morgenstern theory is that it provides an important tool to reach a rational decision. SEU theory and related theories have dominated research on decision making since the mid-1940s, and especially the validity of theories such as SEU theory as adequate *descriptions* of human choice and decision making has been a dominant theme in this research area. This is partly based on the idea that the study of human decision making should focus on the perceptual and cognitive factors that cause human JDM

[†] Deceased.

to *deviate* from the predictions of normative models such as SEU theory.

Violations and Anomalies

Research in the past decades has resulted in many illustrations of systematic violations of principles of rationality. A clear example concerns the violation of the *sure thing principle*: If one prefers one option to another no matter what happens – or has happened – one should prefer that option without knowing what happens, or has happened. Tversky and Shafir (1992) gave an example of violating this principle. Their respondents were asked to consider a gamble with a 50/50 chance of winning $200 or losing $100. Generally, a minority of about one-third of the people offered that gamble accept it. This preference pattern changes dramatically if people are asked to imagine they had already played the gamble and were now being offered the opportunity to play it a second time. In case they were asked to imagine they had won the first time, nearly 70% wanted to play again. If they had been asked to imagine they had lost the first time nearly 60% wished to play it a second time.

Another violation is related to so-called sunk costs. It is Saturday afternoon and you are on the brink of leaving for the railway station in order to get to the football stadium. You bought your ticket for the match some time ago. It is pouring with rain, you do not feel that well and standing in the rain for 2 h is not going to help. In sum, you prefer to spend the afternoon at home. Nevertheless, if you decide not to go, you will have 'wasted' the money you paid for the ticket. The nonrefundable money already paid for the ticket is termed a *sunk cost*. Strictly speaking, there appears to be no rational argument to do things you would prefer not to do in the interest of honoring the sunk cost. However, people often honor sunk costs. Examples include trivial anecdotes such as the one described earlier, but also large-scale enterprises such as the development of the Concorde passenger aircraft (a far too expensive and not very popular aircraft) and the Gulf War (an extremely expensive war with mixed outcomes).

Other violations concern principles such as *transitivity*. If people prefer option A over option B, and also option B over option C, they should also prefer option A over option C. Violations of transitivity may arise from evaluating alternative options in terms of different dimensions. On some dimensions 'A' might be preferred over 'B' and 'C' while on others 'C' might be preferred over 'A.' If the salience of the dimensions varies, preferences could differ and one could violate transitivity. Another way in which transitivity may occur is through regret (see below).

The way in which alternative options are presented can also lead to anomalies. It turns out that people often make different choices as a function of the way alternatives are presented or *framed*, even though the alternatives remain unchanged. One example of framing is to present actions in terms of positive as opposed to negative consequences or vice versa. For example, a 50% chance of a successful outcome of surgery may appear to someone to be a more desirable outcome than a 50% chance of failure. Several studies provide support for this framing effect. (The finding that people often make different choices as a function of how the alternatives are presented and framed.) Framing effects have been extensively investigated in decision problems in which the consequences of options are compared to psychologically salient reference points (e.g., a zero point, the status quo). Kahneman and Tversky (1979) found that when asked to choose between $15 000 for sure or a 50/50 chance of $10 000 or $20 000 most people choose the certain option. If one has received the $20 000 and was asked a second choice between returning $5000 or a 50/50 chance of giving back nothing or $10 000, most people choose the latter option. This pair of choices is contradictory. Similarly, when presented with a choice between a sure loss of $100, or a 50/50 chance of a loss of $200 and a 50/50 chance of no loss at all, most people will prefer the uncertain, risky alternative. This risk-seeking preference is in sharp contrast with preferences when the choice is between a sure gain of $100 or a 50% chance of a gain of $200 and a 50% choice of no gain at all. In this case, most people will prefer the certain, risk-avoiding alternative. According to SEU theory, the two options in each problem are equally (un)attractive. Thus, inducing people to adopt a gain frame when choosing between a gamble and a sure thing tends to result in a risk-avoiding preference (the certain alternative). Inducing people to adopt a loss frame, on the other hand, tends to result in a risk-seeking preference (the risky alternative).

A final anomaly concerns violations of *response invariance*. Choice can also be influenced by the method by which preferences and choices are expressed. An example concerns the effect of choosing versus rejection of alternatives that have both bad and good characteristics. Shafir (1993) argues that a 'choose' orientation leads decision makers to search for good qualities of each option, while a 'reject' orientation makes them focus on bad qualities. Thus, if one alternative has more clear-cut positive *and* negative characteristics, and another alternative is relatively bland, the former could both be chosen and rejected depending on the question. Shafir demonstrated this in the context of awarding custody in which the question was either which parent to *award* custody, or which parent to *deny* sole custody of the child.

Descriptive Approaches to Decision Making

Descriptive theories of human JDM attempt to explain *why* people violate rational choice theory. These descriptive frameworks also view decisions as more reasonable and adaptive than previously thought. Kahneman and Tversky developed *prospect theory* to remedy the descriptive failures of SEU theories of decision making (see Kahneman, 2011). (A theory describing decisions under uncertainty as a function of a value function and a probability function.) Prospect theory attempts to *describe* and explain decisions under uncertainty. Like SEU theories, prospect theory assumes that the value of an option or alternative is calculated as the summed products over specified outcomes. Each product consists of a utility and a weight attached to the objective probability. Both the value function and the probability weighting function are nonlinear. The functions have a number of important features. The most important feature of the probability weighting function is that small probabilities are overweighted and large probabilities are underweighted. The probability weighting function is generally

not well behaved near the endpoints. Extremely low probability outcomes can be exaggerated or ignored entirely. Similarly, small differences between high probability and certainty are sometimes neglected, sometimes accentuated. According to Kahneman and Tversky, this is so because people find it difficult to comprehend and evaluate extreme probabilities.

The value function is defined in terms of gains and losses *relative* to a psychologically neutral reference point. The value function is S-shaped; concave in the region of gains above the reference point, convex in the region of losses (see **Figure 1**). Thus, each unit increase in gain (loss) has decreasing value as gain (loss) increases. In other words, the subjective difference between gaining nothing and gaining $100 is greater than the difference between gaining $100 and gaining $200. Finally, the value function is steeper for losses than for gains. This implies that losing $100 is more unpleasant than gaining $100 is pleasant.

Prospect theory can help to explain the framing effects discussed earlier. The probability function and the value function will confirm the higher attractiveness of the risky option (in case of losses) and the risk-avoiding option (in case of gains).

Other descriptive approaches assume that people rely on a variety of simple decision rules for solving decision problems. Experience will affect the availability of these strategies, and strategy choice will also be affected by the expected advantages (benefits) and disadvantages (costs) of the chosen strategy. For many decisions, an exhaustive analysis such as prescribed by SEU theory simply is not worth the trouble. Thus, for many problems people aim for an acceptable solution and not necessarily the optimal solution due to the costs (time, effort) of 'calculating' the best possible option.

Examples of simplifying decision rules mentioned in the literature are: *the dominance rule* (alternative A should be chosen over B if A is better on at least one attribute and not worse than B on all remaining attributes), *the conjunctive decision rule* (any alternative that does not meet a minimally required value on one or more attributes is dropped from the list of remaining possible alternatives), and *the lexicographic decision rule* (choose alternative which is most attractive on the most important attribute; if two alternatives are equally attractive in terms of the most important attribute move to the next attribute). Finally, the *elimination-by-aspects-rule* is often interpreted as a combination of the lexicographic rule and the conjunctive rule. First, the most important attribute is selected. All alternatives that fail to meet the criterion on this attribute are eliminated. This procedure is repeated for each of the remaining attributes.

Figure 1 Prospect theory: hypothetical value function.

These decision rules require considerably less cognitive effort than the decision rule required by SEU models (a compensatory decision rule which allows negative scores on one attribute to be compensated by positive scores on another attribute). These simplifying rules can provide adequate shortcuts in complex decision environments. Payne et al. (1992) use the term contingent decision making in which the cognitive costs and benefits of the various strategies people might use determine their choice of strategy. Basic questions in this choice concern the balance between cognitive effort and accuracy, but also factors such as decisional avoidance and accountability influence strategy selection. *Heuristics* can also be seen as simplified decision rules; in the next section, we discuss a variety of heuristics that people use when making decisions.

Heuristics

Heuristics are cognitive shortcuts that can be applied consciously or unconsciously to reduce the complexity of decisions. Initially research emphasized the shortcomings of heuristics. The 'heuristics-and-biases' approach showed that people often rely on simple decision rules but that they would be better off – in terms of accuracy – if they would not. This approach goes back to the seminal work of Kahneman and Tversky. The three heuristics that received most attention were *availability*, *representativeness*, and *anchoring and adjustment*. The *availability* heuristic refers to the tendency to assess the probability of an event based on the ease with which instances of that event come to mind. (The tendency to assess the probability of an event based on the ease with which instances of that event come to mind.) Generally people overestimate the probability of an event if concrete instances of that event are easily accessible in memory. Ease of recall and frequency of occurrence are often correlated. A number of factors that affect memory are, however, unrelated to probability. For example, vivid images are easier to recall than pallid ones. Thus having been involved in a serious car accident is likely to be better remembered than annual statistics about the frequency of (types of) traffic accidents. The former is likely to have more impact on probability estimates than the latter.

The *representativeness* heuristic refers to the tendency to assess the probability that a stimulus belongs to a particular class by judging the degree to which that event corresponds to an appropriate mental model. A well-known example of how ignoring prior probabilities can affect judgment was reported by Kahneman and Tversky in 1973 (see Kahneman, 2011). In their study, respondents were provided with brief personality

sketches, supposedly of engineers and lawyers. They were asked to assess the probability that each sketch described a member of one profession or the other. Half the respondents were told the population from which the sketches were drawn consisted of 30 engineers and 70 lawyers, the remaining respondents were told that there were 70 engineers and 30 lawyers. Findings showed that the prior probabilities were essentially ignored, and that respondents estimated the probability of class membership by judging how similar each personality sketch was to their mental model of an engineer or a lawyer.

Anchoring and adjustment refers to a general judgment process in which an initially given or generated response serves as an anchor, and other information is insufficiently used to adjust that response. The anchoring and adjustment heuristic is based on the assumption that people often start their judgmental process by focusing on some initial value that serves as an anchor. The biases related to this heuristic stem from the use of irrelevant anchors and the tendency to insufficiently adjust up or down from an original starting value or anchor.

Initially these three heuristics were described along with a dozen systematic biases such as nonregressive prediction, neglect of base-rate information, and overconfidence. Both heuristics and biases were seen as causing systematic errors in estimates of known quantities and statistical facts. Kahneman and Frederick (see Kahneman, 2011) revised the early conception of heuristics and biases and proposed a new formulation – highlighting a common process of attribute substitution – to explain how heuristics work. Moreover, their new model also includes an explicit treatment of the conditions under which intuitive judgments are modified or overrated by more elaborate cognitive processes. In this new approach, the word heuristic is used in two senses: The noun refers to the cognitive process, and the adjective in *heuristic attribute* specifies the attribute that is substituted in a particular judgment. Kahneman and Frederick added a family of *prototype heuristics* in which an attribute of a prototype is substituted for an extensional attribute of its category; the original instance of a so-called prototype heuristic is the use of representativeness in category prediction we discussed earlier. (A heuristic in which an attribute of a prototype is substituted for an extensional attribute of its category.)

Gigerenzer and colleagues stressed the *adaptive* role of heuristics. In their view, heuristics are efficient cognitive processes that ignore part of the information: Moreover, how well cognitive heuristics function in decisions under uncertainty is in their view an empirical question. Gigerenzer and Gaissmaier (2011) refer to simple, fast, and frugal heuristics that 'make people smart.' (Various classes of adaptive heuristics that people use to make decisions faster, more frugally, and/or more accurately.) They present an overview of the various heuristics people use in different types of situations, and also attempt to answer the question when people should rely on a given heuristic rather than a more complex decision strategy. Gigerenzer and colleagues stress the conscious and deliberate use of heuristics as strategies that ignore information to make decisions faster, more frugally, and/or more accurately than more complex methods. They also refer to less-is-more effects; i.e., when less information or computation leads to more accurate judgments than more information or computation. They thus disagree with the view of Payne et al. (1992) that people rely on heuristics because information search and computation costs time and effort, and that heuristics save time and effort at the expense of accuracy.

A first class of heuristics introduced by Gigerenzer and colleagues can be related to an important capacity of our memory; i.e., the fact that a sense of recognition appears in consciousness earlier than recollection. The *recognition* heuristic simply states that if one of two alternatives is recognized and the other is not, then one should infer that the recognized alternative has the higher value with respect to the criterion. An example is name recognition of cities; this turns out to be a reasonably valid predictor of their population. The higher the recognition validity (α) for a given criterion, the more ecologically rational it is to rely on the recognition heuristic. For each individual, α can be computed by $\alpha = C/(C + W)$ where C is the number of correct inferences the recognition heuristic would make, computed across all pairs in which one alternative is recognized and the other is not, and W is the number of wrong inferences.

The *fluency* heuristic states that if both alternatives are recognized but one is recognized faster, then infer that this alternative has the higher value with respect to the criterion. The fluency heuristic is ecologically rational if the speed of recognition is correlated with the criterion. Fluency also plays a role when alternatives are not given but need to be generated from memory. Johnson and Raab (2003) introduced the *take-the-first* heuristic: Choose the first alternative that comes to mind. They tested the ecological validity of this approach with experienced handball players when choosing how to proceed in a given situation (e.g., pass the ball to another player, or take a shot). A third class of heuristics are so-called *one-reason* decisions: a class of heuristics that bases judgments on one good reason only, ignoring other cues. Obviously this heuristic is related to the lexicographic decision rule: The latter is defined in terms of the 'most important' attribute. *One-clever-clue* heuristics (an example of one-reason decision making) focuss on the usefulness and predictive value of the selected cue of the overall outcome of the choice. Similarly, the *take-the-best* heuristic is a model of how people infer which of two alternatives has a higher value on a criterion, based on binary cue values retrieved from memory. Take-the-best consists of three steps: (1) search through cues in order of their validity, (2) stop on finding the first cue that discriminates between the alternatives, and (3) the alternative with the more positive cue value has the higher criterion value.

Karelaia (2006) showed that a *confirmatory stopping rule* – stop after two cues are found that point to the same alternative – leads to quite robust results. This heuristic tends to be ecologically valid in situations where the decision maker knows little about the validity of cues. This class of heuristics weighs cues or alternatives equally and thus makes simple trade-offs. Tallying is an example. *Tallying* entails simply counting the number of cues favoring one alternative in comparison to others. In three steps: (1) search through cues, (2) stopping rule: if the number of cues is the same for both alternatives, search for another cue. If no more cues are found, guess. Otherwise (3) decide for the alternative that is favored by more cues.

Basically Gigerenzer's work showed that heuristics are not good or bad and – in some circumstances – can be more

accurate than more complex strategies. More research is needed on how people learn to use heuristics in an adaptive way; i.e., when to use the proper strategy from their adaptive heuristic tool box.

In their review article on heuristic decision making, Gigerenzer and Gaissmaier (2011) also ask whether gut feelings are based on heuristics, and if so, on which? This brings us to the distinction between intuitive versus deliberative decision making.

Intuition versus Deliberation and Reasoning

Kahneman (2003) related the research he and Amos Tversky conducted on heuristics-and-biases to two generic modes of cognitive function: an intuitive mode in which judgments and decisions are made automatically and rapidly (Systems 1), and a controlled mode, which is deliberate and slower (System 2).

An illustration of the differences between System 1 and System 2 is provided by Kahneman in his seminal work *Thinking, fast and slow*, published in 2011. Two characteristics of System 1 are the neglect of duration and the peak-end rule (the global retrospective ratings of pain or pleasure are well predicted by the average level of pain/pleasure reported at the worst moment of the experience and at its end). According to System 2, duration is important. This is not the case in System 1. As a consequence people sometimes favor suboptimal outcomes. An example is that people generally prefer a short period of intense joy over a long period of moderate happiness. Similarly, we fear a short period of intense pain more than a much longer period of moderate pain.

System 2 is characterized by processes that are slow, serial, controlled, effortful, rule-governed, flexible, and neutral. The more intuitive System 1 is characterized by processes that are fast, parallel, automatic, effortless, associative, slow-learning, and emotional. Kahneman argued that highly accessible impressions produced by System 1 control judgments and preferences, unless modified or overruled by more elaborate and deliberate operations in System 2.

Psychologists differ in their definitions of intuition, but there is general agreement that intuition tends to rely on information acquired without conscious and deliberative reasoning. Betsch (2008) puts it as follows:

> "Intuition is a process of thinking. The input to this process is mostly provided by knowledge stored in long-term memory that has been primarily acquired via associative learning. The input is processed automatically and without conscious awareness. The output of the process is a feeling that can serve as a basis for judgments and decisions" (p. 4).

(A more or less automatic process of thinking based on knowledge stored in long-term memory that has primarily been acquired via associative learning.) Deliberation in contrast, is described as a strategy in which "Information is integrated in a serial manner, processing is cognitively demanding and rather slow, and individuals using these strategies are aware of most of the underlying processes and can even verbalize them" (p. 6). There is growing evidence that people can unconsciously integrate large amounts of information, and integrate them to come to summary evaluations or feelings (Betsch and Glöckner, 2010). Intuitions based on these experiences can also be remarkably accurate.

Heuristics (as mentioned in the preceding paragraph) are obviously related to intuition (Gigerenzer and Gaissmaier, 2011; Kahneman, 2003), but some argue that they do not fit the above definition of intuition. For instance, decisions based on heuristics tend to ignore rather than integrate multiple pieces of information and deliberated judgments more often rely on heuristics than judgments made intuitively (see Plessner et al., 2008). Unconscious thought theory (Dijksterhuis and Nordgren, 2006) is also associated with intuition. Unconscious thought theory claims that people can make superior decisions after a period of distraction in which they unconsciously address the judgment task. However, some of its assumptions and claims are controversial.

Affect, Emotion, and Decision Making

The first decades of research on decision making were dominated by cognitive approaches. Individual decision makers were assumed to assess the likelihood and value of the possible consequences of their actions rather dispassionately, as described earlier in this overview. People were assumed to opt for actions that maximize the overall utility of the various possible outcomes; and violations from the principle of utility maximalization were explained in terms of cognitive errors and shortcomings. The various heuristics people employed were seen as cognitive shortcuts that help to cope with the complexity of decisions. As argued by Loewenstein and Lerner (2003), the literature generally ignored the role of emotions in JDM. There are a few exceptions. One of them is *regret theory*. The basic idea underlying this approach is that the value placed on the outcome of a specific choice or gamble also depends on the outcome that *would* have been received if one had chosen an alternative choice or gamble. Thus winning $100 is likely to be affected by the knowledge that one could have won $500 (vs e.g., $10) if one had selected another alternative. Basically, regret theory posits that people *anticipate* the possibility of regret and that this anticipation affects their decision making. People not only want to maximize utility, they also want to minimize the possibility of regret.

Regret is a rather cognitive emotion since it relies on comparing different outcomes, but regret theory was one of the first to explicitly incorporate emotions in explanations of human decision making. It needs to be added that robust and systematic effects of regret have mainly been obtained when the possibility of regretful outcomes are made salient. Another example is the anticipation of *disappointment*. When disappointment is anticipated, it has an effect on judgment and choice; people generally want to minimize the possibility of disappointment. In sum, anticipated emotions can affect decision making but they need to be salient before the decision is made.

Other research focused on the influence of *immediate* affect, as opposed to *anticipated* affect. First, low and moderate levels of affective intensity can serve in an 'advisory' role without altering the perception of the various attributes

underlying a decision (probabilities, values). An example is the *affect-as-information* model in which people rely on subjective assessments of their feelings ('How do I feel about it?') and judge accordingly. Emotions – particularly when they are more intense – can override deliberative cognitive processing. For example 'gut feelings' often determine the acceptability of technological hazards (see e.g., Slovic et al., 2002).

As shown by Loewenstein and others, immediate emotions also have an impact on how people feel about future outcomes. Thus people tend to project their current feeling state on to the future; when people are in a 'cold' state (e.g., not hungry, not tired, not sexually aroused, not angry) they tend to underestimate the impact of these states and their effect on judgment and choice. Loewenstein termed these 'hot/cold empathy gaps.' Emotions not only exert an influence on *how* people judge and weigh expected consequences, but also on the *quality* of information processing. Generally, negative emotions narrow attentional focus, while positive emotions tend to broaden attentional focus. Positive emotions are also generally associated with less thorough information processing.

As argued by Loewenstein and Lerner (2003), emotions are now firmly embedded in the decision-making literature. In the past, emotions were associated with maladaptive strategies and faulty decision making. Now we know that emotions serve an essential function in coordinating cognition and behavior and that ignoring emotions can have detrimental effects on the quality of our decision making. An important benefit of expected emotions is that we employ a broader perspective when assessing the outcomes of a decision. This can be quite functional, if we focus on the right emotions and assess them adequately. Immediate affect that is experienced at the time of making a decision can help to prioritize information processing and make specific consequences of the decision more salient; unfortunately it can also steer decisions in directions that are counter to self-interest. For example, fear may make people more aware of risk, but it may also make them excessively risk averse. Another example is that experimentally induced fear and anger have opposing effects on the perception of risk. Angry people tend to perceive less risk than people who are in a state of fear. All in all, emotions can have a profound impact on decisions.

Conclusions

Nearly seven decades after the seminal work of Edwards (1954), decision-making research is becoming more prominent in psychology textbooks and a clear and separate research area has emerged, generally referred to as *behavioral decision research*, or JDM. An important characteristic of this field of inquiry is that it relies on concepts, models, and methods from a variety of disciplines including economics, statistics, and social and cognitive psychology. Research on decision making pays considerable attention to the discrepancies between normative models and actual behavior. Most of the research attempting to account for these discrepancies focused on the information processing strategies, or heuristics, that people use when making judgments or decisions. A variety of descriptive approaches to human decision making has improved our insight into the cognitive processes underlying decisions and should also help to improve the quality of decision making. Recent advances in this field of research show the important role of anticipated and felt emotions on decision making. The field now generally distinguishes between more analytical and deliberative decision modes, and more intuitive decision modes. Affect and emotion play an important role in the latter. Research on the interplay between cognition and affect is likely to help improve our understanding of human decision making.

Abstract

An important finding of neuropsychological studies is that memory is not a single entity but is composed of several different forms that rely on separate brain systems. The major distinction is between conscious knowledge of facts and events, referred to as declarative or explicit memory, and nonconscious knowledge systems that provide for the capacity of skill learning, habit formation, the phenomenon of priming, and certain other ways of interacting with the world, collectively referred to as nondeclarative or implicit memory. Declarative memory is dependent on the integrity of the hippocampus and anatomically related structures in the medial temporal lobe and diencephalon. It seems to be especially good at associating the various aspects of a context that are present at a particular time and place, thereby creating a memory of an episode. A particularly good example of declarative memory involves the ability to identify a recently encountered item as familiar, a capacity termed as recognition memory. Declarative memory is the kind of memory impaired in amnesia. Other characteristics of this form of memory have emerged from studies with experimental animals. Declarative memory is fast and is flexible in the sense that it is accessible to multiple response systems. It is especially suited for one-trial learning, and for forming and maintaining associations between arbitrarily different pieces of material.

Introduction

Many important aspects of the neurobiology of memory involve systems-level questions that can be addressed at a relatively global, neuropsychological level of analysis. Two long-standing and interrelated questions have been of central interest since the 1960s. The first is whether there is more than one kind of memory. The second concerns what brain structures and pathways are involved in memory. Scientific work on these issues has introduced the term declarative memory to neuroscience and identified a number of parallels between the neural organization of memory in humans and animals.

It has turned out that the brain is organized such that memory is a distinct and separate cognitive function, which can be studied in isolation from perception and other intellectual abilities. Significant information about how memory is organized has come from two experimental approaches. First, the study of patients with memory disorders (amnesia) has been enormously useful. Second, information about the anatomy of memory has come mainly from the kind of systematic and cumulative work that is possible only in experimental animals.

Amnesia and the Medial Temporal Lobe Memory System

Amnesia refers to difficulty in learning new information or in remembering the past. Amnesia can occur as a strikingly circumscribed memory impairment in the absence of other cognitive deficits (Scoville and Milner, 1957). Patients with this disorder can have intact intelligence test scores, intact language and social skills, and an intact memory for a great deal of information from the remote past, especially childhood. In addition, immediate memory is intact. Indeed, patients can hold information in mind for several minutes, provided there is no distraction and the material can be rehearsed. Their intact immediate memory explains why amnesic patients can carry on a conversation and can appear quite normal to casual observation. The difficulty for individuals with amnesia arises when information must be recalled after a distraction-filled interval, or when recall is attempted after the presentation of an amount of information that exceeds immediate memory capacity (e.g., eight or more digits or four or more objects). In this situation, normal individuals will usually recall more items than amnesic patients.

An animal model of human amnesia was established in the monkey in the early 1980s (Mishkin, 1982; Squire and Zola-Morgan, 1983). Systematic and cumulative work during the subsequent 10 years, using the animal model, succeeded in identifying the system of structures in the medial temporal lobe essential for memory (Squire and Zola-Morgan, 1991) (Figure 1). This system includes the hippocampal region (i.e., the hippocampus proper, the dentate gyrus, and the subicular complex), the entorhinal cortex, and the adjacent perirhinal and parahippocampal cortices. Since that time, a number of studies in monkeys have been carried out, comparing performance on memory tasks in monkeys with damage to different components of the medial temporal lobe. This work has shown that the severity of memory impairment depends on the locus and extent of damage within the medial temporal lobe memory system. Damage limited to the hippocampal region causes significant memory impairment, but additional damage to the adjacent cortex increases the severity of memory impairment. It is important to note that the discovery that larger medial temporal lobe lesions produce more severe amnesia than smaller lesions is compatible with the idea that structures within the medial temporal lobe might make qualitatively different contributions to memory function. This is because anatomical projections carrying information from different parts of the neocortex enter the medial temporal lobe memory system at different points (Suzuki and Amaral, 1994).

Another important brain area for declarative memory is the diencephalon. The important structures include the mediodorsal thalamic nucleus, the anterior thalamic nucleus, the

Figure 1 Schematic view of the medial temporal lobe system. The perirhinal and parahippocampal cortices receive projections from unimodal and polymodal areas in the frontal, temporal, and parietal lobes. In turn, the perirhinal and parahippocampal cortices account for nearly two-thirds of the cortical input to the entorhinal cortex the primary source of cortical input to the hippocampal region (i.e., the cell fields of the hippocampus proper, the dentate gyrus, and the subicular complex). The hippocampal region together with the entorhinal cortex makes up the hippocampal formation. The entorhinal cortex also receives other direct inputs from orbital frontal cortex, cingulate cortex, insular cortex, and superior temporal gyrus. All these projections are reciprocal.

internal medullary lamina, the mammillothalamic tract, and the mammillary nuclei. Because diencephalic amnesia resembles medial temporal lobe amnesia in many ways, these two regions likely form an anatomically linked, functional system.

At about the same time that an animal model of amnesia was established, detailed case studies of human amnesia provided extensive neuropsychological information about memory impairment, as well as detailed neuropathological information about the locus and extent of damage in each patient's brain. Recent developments in brain imaging techniques have also made it possible to detect some kinds of neuropathology in living patients. The available neuroanatomical information from humans is consistent with the findings from monkeys. These lines of work have greatly clarified the different forms of memory and their anatomical basis, and have made it possible to pursue parallel work in simpler animals such as rats and mice. As a result, one can now study memory in rodents and have some confidence that what one learns can be relevant to the human condition.

Declarative Memory

An important finding from neuropsychological studies of memory is that memory is not a single entity but is composed of several separate systems (Squire, 1992; Schacter and Tulving, 1994). Figure 2 illustrates how long-term memory can be divided into several parallel memory systems. The major distinction is between conscious knowledge of facts and events, referred to as declarative or explicit memory, and other nonconscious knowledge systems that provide for the capacity of skill learning, habit formation, the phenomenon of priming, and certain other ways of interacting with the world, collectively referred to as nondeclarative or implicit memory. Nondeclarative memory is not itself a brain-systems construct. Rather, this term encompasses several different kinds of memory. Nondeclarative forms of memory have in common the feature that memory is nonconscious. Memory is expressed through performance and does not require reflection on the past or even the knowledge that memory is being influenced by past events.

Declarative memory (explicit memory, relational memory) is a brain-systems construct, referring to the capacity for conscious recollections about facts and events that is dependent on the integrity of the hippocampus and anatomically related structures in the medial temporal lobe and diencephalon. Declarative memory seems to be especially good at associating the various aspects of a context that are present at a particular time and place, thereby creating a memory of an episode. Declarative memory is also well suited for connecting the pieces of information needed to acquire a new fact (e.g., the capital of North Dakota is Bismarck). It is sometimes pointed out that declarative memory allows one to model the external world, and it is either true or false; nondeclarative memory is about performance, and it is neither true nor false.

Declarative memory is the kind of memory impaired in amnesia. However, the concept of declarative memory is not defined solely in terms of what amnesic patients can and cannot learn. Other characteristics of declarative memory have also been identified. For example, work with amnesic patients

Figure 2 A taxonomy of mammalian long-term memory systems. The taxonomy lists the brain structures thought to be especially important for each form of declarative and nondeclarative memory. In addition to its central role in emotional learning the amygdala is able to modulate the strength of both declarative and nondeclarative memories.

has emphasized the notion of conscious recollection, though this description is unhelpful when considering learning and memory in animals. Other characteristics have emerged from the studies of experimental animals. Declarative memory is fast, it is not always reliable (i.e., forgetting and retrieval failure can occur), and it is flexible in the sense that it is accessible to multiple response systems. It is especially suited for one-trial learning, as well as forming and maintaining associations between arbitrarily different pieces of material.

Recognition Memory

A particularly good example of declarative memory involves the capacity to identify a recently encountered item as familiar, a capacity termed recognition memory. Recognition memory is impaired in amnesic patients, and it is impaired in monkeys and rodents following damage to the hippocampal region. The assessment of recognition memory in animals has depended mainly on two behavioral tasks, delayed nonmatching to sample and novel object recognition. In delayed nonmatching to sample, two objects are presented, a new one and one that was presented earlier. The animal must choose the new object in order to obtain a food or liquid reward. In the novel object task, as adapted for the monkey, a new picture and a recently presented picture are presented side by side, and the monkey's spontaneous tendency to look at the new picture is measured. When this task is administered to rodents, the animal's tendency to explore novel objects over recently encountered objects is measured. Similar to humans, monkeys and rats have an innate preference for novelty, and by showing a preference for viewing the new picture or exploring the new object, the animal is demonstrating that it remembers the old, and now less interesting stimulus.

Studies in humans, monkeys, and rodents with selective hippocampal lesions document impairment in these tasks. Although there have been some studies in which no impairment on these tasks was detected after hippocampal damage, there are considerable data to suggest that the hippocampus is critical for recognition memory performance (Squire et al., 2007 for review, Zola et al., 2000). Recent studies have identified neural signals within the hippocampus in both monkeys and humans that might underlie or support recognition memory performance (Jutras and Buffalo, 2010; Rutishauser et al., 2006). When the hippocampal damage occurs together with damage to adjacent cortices, including the perirhinal cortex, the impairment is more severe. The evidence that the hippocampal region is essential for normal recognition memory is entirely consistent with current ideas about the role of the hippocampus in declarative memory and with the view that the hippocampus is essential for acquiring information about relationships, combinations, and conjunctions among and between stimuli (Manns and Eichenbaum, 2006). The recognition tests ask whether an item that had been presented recently now appears familiar. A recognition (or familiarity) decision requires that the stimulus presented in the retention test be identified as what was presented during learning. At the time of learning a link must therefore be made between the to-be-remembered stimulus and its context or between the stimulus and the animal's interaction with it. It is this associating and the ability to retain relational information across time that many have supposed is at the heart of declarative memory and in turn is the function of the hippocampal region in both humans and nonhuman animals.

Episodic and Semantic Memories

Episodic memory refers to the capacity for recollecting an autobiographical memory of events that occurred in a particular spatial and temporal context. Semantic memory refers to the capacity for recollecting general knowledge and facts about the world. Both types of memory are declarative in the sense

that subjects are retrieving information explicitly, and they are aware that stored information is being retrieved. There is good agreement that episodic memory is impaired in amnesia following damage to the medial temporal lobe memory system. However, there is less agreement about semantic memory. By some accounts, amnesic patients are proportionately impaired in both episodic and semantic memory. By other accounts, the capacity for semantic memory is spared, or partially spared in amnesia relative to episodic memory ability, especially if the damage is limited to the hippocampal region.

Evidence for the second view comes especially from cases where amnesia occurred in early childhood, before much of an individual's semantic knowledge has been acquired (Vargha-Khadem et al., 1997). While these individuals have severe impairment in episodic memory, they show some ability to acquire semantic knowledge, albeit at an impoverished rate. Taken together, the data tend to favor the view that episodic and semantic memories are similarly impaired in amnesia (Squire and Zola, 1998). Other work suggests that episodic memory additionally depends on the frontal lobes, which provide a source of autobiographical involvement with the recollected material. This orientation allows for a fundamental distinction between episodic and semantic memory, without depending on differences in the anatomical basis of the two kinds of memory within medial temporal lobe structures.

Overview

Work with amnesic patients and experimental animals have converged to characterize the organization of declarative memory. Declarative memory depends on the integrity of the medial temporal lobe, which works in concert with the neocortex. Declarative memory may develop gradually from early in life. Human infants 6 months of age successfully perform the novel object recognition task, and performance on this task is impaired by hippocampal lesions in humans and monkeys. The view that some declarative memory is available early in life is also consistent with demonstrations of long-term, recall-like memory abilities in human infants.

Other work with amnesic patients has suggested that declarative memory is equivalently involved in the two fundamental processes of recall and recognition. Work in humans and animals has shown that the medial temporal lobe memory system is required at the time of learning if an enduring and retrievable long-term declarative memory is to be established. Studies of retrograde amnesia in amnesic patients and in experimental animals suggest that the brain system supporting declarative memory has a time-limited function. Medial temporal lobe lesions spare very remote memories. Thus, as time passes after learning, a process of consolidation and reorganization occurs such that permanent storage does not require the medial temporal lobe. Permanent memory is thought to be stored in a distributed way throughout the neocortex where information is received and processed. Information is still accumulating about how memory is organized, what structures and connections are involved, and what functions they support. The disciplines of both psychology and neuroscience continue to contribute to this enterprise.

Deconstruction

Abstract

Deconstruction is a mode of philosophical and literary analysis derived from the work of the French philosopher Jacques Derrida that questions the most basic philosophical categories or concepts. In philosophy, it involves the undoing of fundamental oppositions through a demonstration that they are constructions, not part of the nature of things but categories imposed by discourses that provide the evidence for their deconstruction. Beyond philosophy, deconstruction influenced work in fields such as law, anthropology, psychoanalysis, theology, and gender studies by providing an impetus to treat the categories and the metalanguage of a discipline as interested constructions rather than as a neutral framework, and by encouraging attention to the rhetorical and performative dimensions of texts as well as to their explicit arguments.

Deconstruction is a mode of philosophical and literary analysis, derived from the work of the French philosopher Jacques Derrida that questions the most basic philosophical categories or concepts. In the 1970s, the term was applied to analyses, by Derrida and others, of philosophical and literary writings. In the 1980s, it came to designate more loosely a range of radical theoretical enterprises in diverse areas of the humanities and social sciences, including law, psychoanalysis, architecture, theology, feminism, gay and lesbian studies, historiography, and political theory. What these enterprises shared was a critical dismantling of the conceptual oppositions that had previously been regarded as fundamental to the disciplines in question. The term *deconstruction* was one of the flash points in critical and cultural debates of the last quarter of the twentieth century, a rallying point and term of abuse, the name of a body of difficult, deeply influential theoretical writings, and also the name for a broad movement in twentieth-century thought in which assumptions or presumptions of a millennial philosophical, literary, and critical tradition have been put in question. Although the term primarily designates a mode of analysis derived from the work of Jacques Derrida, *deconstruction* has somewhat surprisingly entered popular usage: in July 2007, when Barry Bonds was on pace to break the record for home runs in Major League Baseball, the sports section of the *New York Times* reported "Bonds spent his free time in Chicago praying with Jesse Jackson, visiting with his family, and deconstructing videotape of his swing."

Deconstruction has thus entered the language, as a synonym for analysis that exposes mechanisms, procedures, or habits, though its connotations do not appear to be settled. Woody Allen's film *Deconstructing Harry* announces a dismantling or undoing that does not bode well for Harry, whereas the *Times* report suggests that Bond's deconstructive analysis provided insights into his swing and enabled him 'to correct some flaws.' In general, the term has come to designate a critical dismantling or undoing: in fashion, for example, a 'deconstructed jacket' is one in which various parts are clearly displayed as parts. However, in polemics about late twentieth-century thought, 'deconstruction' is sometimes used as a pejorative synonym for 'post-structuralism' or 'postmodernism' – one that suggests nihilism or frivolous skepticism.

Deconstruction and Philosophy

Deconstruction undertakes a radical critique of fundamental categories of Western thought by exploring how these categories have been constructed in and by the discourses that rely on them. It is a mode of analysis that examines not only the arguments of philosophical texts but also the rhetorical procedures and devices they employ and the tensions or contradictions between what is claimed or assumed and what the texts themselves must do in order to support such claims. A major focus of deconstruction has been the traditional binary oppositions that have structured Western thought since the time of the Greeks: for example, the oppositions between inside and outside, mind and body, literal and metaphorical, speech and writing, presence and absence, nature and culture, intelligible and sensible, form and meaning. Each of these oppositions is hierarchical, in the sense that one of its terms has been taken to be primary and fundamental, and the other secondary and derivative (Derrida, 1981). Thus, nature is logically prior to culture; writing is seen as merely a way of representing speech, which is taken to be the basic form of language; meaning is what comes first and is then given expression by form.

A deconstruction of these oppositions asks how the philosophical enterprise and thought in general have relied upon the privileging of one term and invites us to consider whether in fact such hierarchies should not be revised. In particular, a deconstruction questions these hierarchical oppositions by showing how they have been constructed and, in the process, undoing that construction and establishing a new relation between the terms. It can be shown, for example, that the idea of 'nature' is a product of culture: conceiving something as prior to culture is a specific cultural operation whose import and function need to be assessed. In the opposition between nature and culture, the primacy of nature cannot, therefore, be taken for granted. What we have, rather, is an opposition elaborated within culture; what counts as nature in any historical moment will be a fact about that culture. To argue in this way is to invert and restructure the opposition (to 'displace' it) in a way characteristic of deconstruction. Instead of a primary nature and a secondary culture, we discover a variable distinction between nature and culture within culture.

For Derrida, the most telling and pervasive opposition has been the one that treats writing as secondary or derivative with respect to speech. According to this opposition, in speech the ideas and intentions of the speaker are immediately present; it is a direct and authentic form of language, whereas writing is merely a graphic representation of the spoken word (a sign of a sign) and hence marked by absence and possibilities of discrepancies between form and meaning (Derrida, 1976). By setting aside writing as a secondary and derivative, a mere representation open to misunderstanding, accounts of language have taken as their object an idealized form of speech, where the linguistic form is a direct expression of what the speaker, as we say, 'has in mind.' But Derrida argues that linguistic forms can function as signs only to the extent that they can be repeated in different contexts, in the absence of any particular speaker's presence or intention (Derrida, 1988). Speech is only possible, in other words, to the extent that it has the qualities assigned to writing, such as absence, difference, and the possibility of misunderstanding. One mark of this, Derrida has shown, is the frequent recourse, in attempts to describe speech, of examples and metaphors drawn from writing. In effect, speech has been described as a form of writing, even when the claim has been that writing is derivative from speech (Derrida, 1976). This deconstruction of the traditional hierarchical opposition between speech and writing argues not that there are no differences between speech and writing but that the traditional opposition is untenable and that both speech and writing are forms of a general writing (*archi-écriture*), which is the condition of possibility for any system of representation whatsoever.

Derrida argues that treating writing as secondary to speech is part of what he calls the 'logocentrism' of Western culture: the presumption of an order of truth or thought prior to its representation by signs (Derrida, 1976). Logocentrism tries to treat representation as inessential rather inextricably involved in the structure of phenomena, but an attentive reading of the texts of the philosophical tradition shows that they tell a different story. Derrida's work attempts to demonstrate that discourses that treat writing as secondary in fact must make use of notions linked to writing when they characterize speech and that thus speech can be seen as a version of a generalized writing, which is the condition of language and thought in general. This is an instance of the deconstruction of concepts seen as fundamental, such as 'presence,' 'truth,' 'origin,' and 'identity.'

Deconstruction may be conceived in the first instance as a critique of Western philosophy. Philosophy, Derrida argues, has been founded on a theory of 'presence,' in which such notions as truth, being, and reality are determined in relation to an ontological center, essence, or origin, based on the repression of absence and difference. But since deconstruction works not by erecting an alternative theory but by exploring how philosophical discourses have produced their concepts through rhetorical stratagems, it entails powerful practice of reading, which illuminates how texts implicitly put in question what they explicitly maintain or what they appear to assume. It has been called "a careful teasing out of warring forces of signification within a text" (B. Johnson 1980: p. 5).

Deconstruction is not, Derrida insists, a school or a method, a philosophy or a practice, but something that happens, as when the arguments of a text undercut the presuppositions on which it relies, or as when the term *deconstruction* (*déconstruction*), which Derrida introduced somewhat casually as a French translation of the terms *Abbau* and *Destruktion* ('unbuilding' and 'destruction') in Martin Heidegger's philosophical writing, takes on a life of its own, escaping the control of the author and coming to refer to a broad intellectual process or movement that the end of the twentieth century by no means exhausted.

Deconstruction arises from the continental tradition in philosophy rather than the analytical tradition. Analytic philosophers have generally been resistant to deconstruction and to Derrida, even to the point of excluding him from philosophy and associating him with literary theorists, but some analytical philosophers have successfully recast Derrida's arguments in the idiom of analytic philosophy (Bearn, 1995; Wheeler, 2000). Other philosophers working in the continental tradition have sought to rescue Derrida from literary theory and to recapture him for the tradition of continental philosophy as a systematic philosopher in a traditional mode (Gasché, 1988). Bennington provides both a systematic description of his thought (Bennington and Derrida, 1993) and analysis of philosophical responses to Derrida's work (2000).

Deconstruction and Literary Studies

In the 1970s and 1980s, deconstruction played a major role in the animation and transformation of literary studies by what was called simply 'theory,' for short. Briefly stated, 'theory' is concerned with questions about the nature of language, the production of meaning, or the relations between literature and the numerous discourses that structure human experience and its histories. In the United States, deconstruction was associated in particular with a group of scholars at Yale University, where Derrida taught regularly as a visiting professor. In the hands of Paul de Man and Barbara Johnson, for instance, deconstruction became a powerful practice of rhetorical reading, attentive to the rhetorical strategies and figurative structures of literary works, to what is at stake in texts of all sorts and to how texts engage those stakes.

Because Derrida does philosophy by reading texts slowly, with virtuoso resourcefulness, attentive to their rhetorical strategies and ideological investments, his work appealed to students and teachers of literature, who found in it close reading that (1) was not subservient to the ideological notion of organic form that underlay the most widespread practice of close reading, that of the New Criticism (the name generally applied to the major school of literary analysis in the United States and United Kingdom from the 1960s on), and (2) showed that philosophically significant issues are at play in these texts: the oppositions that they engage structure thinking about fundamental questions.

Deconstructive literary criticism was often compared, especially by its critics, to an earlier Anglo-American New Criticism that sought to explicate and appreciate verbal works of art as complex constructions and emphasized the role of paradox and irony in these intricate artifacts. However, deconstructive readings, by critics such as those mentioned above, differ in several ways (Culler, 2007). They treat works of art not as the harmonious fusion of form and content but as instances of the

intractable conflicts between modes of meaning. They generally examine the individual work not as a self-contained artifact but a product of relations with other texts or discourses, literary and nonliterary. Finally, they are especially interested in the ways in which the works may offer implicit critiques of the categories critics use to analyze them.

If in the twenty-first century there are fewer critical studies devoted to showing how literary works subvert the premises on which they rely or the meanings they have been presumed by the earlier critical tradition to articulate, deconstruction has come to be broadly diffused within literary studies, so that conceptions associated with deconstruction (the critique of the idea of organic form, for instance, and the notion that writing about literature should explore how it engages the presuppositions on which it relies) have become very widespread.

The most distinctive deconstructive work by critics such as de Man and B. Johnson explores literary works' engagement with major philosophical stakes (de Man 1979). Johnson, author of incisive, elegant deconstructive essays on poets and novelists (Johnson 1980), broadened her engagement with psychoanalysis, women's writing, feminist theory, African-American literature, and cultural studies, in ways indicative of the expansive influence of deconstruction. Two essays that might be cited as exemplary of deconstructive reading are 'Anthropomorphism in Lyric and Law,' and 'Muteness Envy.' The former brilliantly brings together de Man's analysis of the trope of anthropomorphism that takes the human for granted in treating something as human and is central to the functioning of lyric poetry, and the anthropomorphizing operations at issue in legal debates. The determination of what the law will treat as a person – what entities or organizations are deemed to have the rights of a person – has immense consequences for the allocation of social privileges and resources, and an account of the rhetoric of legal reasoning in this realm proves extremely illuminating (Johnson, 2008). 'Muteness Envy' reads Keats's 'Ode on a Grecian Urn,' with its 'still unravished bride of quietness,' against Jane Campion's film *The Piano* and the critical reception of the film, so as to explore the cultural construction and aestheticization of female muteness as a repository of feminine value. Johnson concludes that the work performed by the idealization of women's silence is that it helps culture not to be able to tell the difference between women's pleasure and their violation, a problem at issue in *The Piano* and the debates about it (Johnson, 1998). This is an example of efficient deconstructive reading engaging a variety of cultural texts on issues of great moment.

Derrida himself wrote extensively about literary works (Derrida, 1992), in what one critic calls "the most significant, far-reaching, and inventive exploration of literature for our time" (Attridge, 2004: p. 139); but the mode of these essays is different from the exploration of binary oppositions characteristic of what is called deconstruction. Pursuing particular motifs rather than offering interpretations of a work as a whole, Derrida addresses the work's attempt to be a singular event.

During what were called 'the culture wars' of the 1980s and 1990s in the United States, people combatting pressures to open the canon to works by women, members of minority groups, and Third World cultures or moves to reject high culture in favor of popular culture, sometimes seized upon the term *deconstruction* to label the developments that they saw as threatening Western civilization itself. In fact, deconstructive critics, despite their sympathies with movements to broaden the canon, were deeply engaged with the texts of the high cultural tradition, from Plato to Proust, which they saw as particularly savvy and enlightened, richer, and more subversive than readers had previously realized. They were scarcely agitating to substitute soap operas for Shakespeare: the desire to teach popular culture or to substitute non-Western texts for historically crucial works of the Western tradition came from practitioners of cultural studies, who often saw deconstruction as a dangerous, elitist enemy, committed to high culture, engaged with difficult philosophical texts and their specialized jargon, and valuing difficulty and complexity.

Deconstruction Beyond Philosophy and Literature

Critics of deconstruction have tended to attack it either as obscurantist wordplay, excessively invested in supposedly minor or marginal rhetorical features of texts and cast in language that obfuscates rather than illuminates, or as a nihilistic denial of authority, certainty, and foundations, for which 'anything goes' (Ellis, 1989). But despite attacks, the impact of deconstruction on modern thought, not just literary studies, has been extensive. Most generally, it has encouraged the questioning of the hierarchical oppositions that structure any field of inquiry and an interest in whether and how these fundamental oppositions are subverted by the phenomena that they are used to describe. Deconstruction is thus a powerful version of the general critique of supposedly scientific metalanguages – sets of terms or concepts used to analyze a domain and which are regarded as external to the phenomena they purport to analyze. Deconstructive analyses explore the ways in which the supposedly neutral or purportedly scientific metalanguage is deeply affected by the phenomena it is supposed to analyze. Thus, it might show, for instance, that the terms deployed by theory of metaphor or figurative language generally are themselves scarcely free of metaphor or explore how a psychoanalytic theory is itself affected by the mechanisms of repression and wish fulfillment it purports to analyze (Derrida, 1987). Since within literary and cultural studies, it was above all structuralism (*see* Structuralism) that sought to elaborate metalanguages for analyzing cultural phenomena as a series of languages or signifying systems, the deconstructive critique of the possibility of a neutral metalanguage was seen as a step-beyond structuralism and hence as a case of 'post-structuralism.'

There are two main aspects to the influence of deconstruction outside of literary and philosophical studies. On the one hand, granting primacy not to what a text 'says' but, rather, to how what it 'does' relates to what it says, deconstruction emphasizes that rhetorical structures are centrally at work in language of all sorts and that discourse has an important 'performative' dimension, structuring experience in particular ways. It thus seconds and invigorates the constructivist tendencies of numerous disciplines: the attempt to show how that the phenomena studied by a discipline are not simply given to experience but are produced by conceptual frameworks and discursive practices. On the other hand, as a critical exploration of fundamental oppositions and an attempt to intervene and alter the value attributed to particular terms,

deconstructive thinking has affected not just how texts are read but the sense of what a discipline's goal might be.

Deconstruction and Psychoanalysis

In psychoanalysis, for instance, deconstructive readings of texts by Sigmund Freud and such successors as Jacques Lacan have done several things:

1. focused on the structuring role of language in the formation of the psyche;
2. shown how psychoanalytic case studies are themselves structured by the kinds of psychic mechanisms that they purport to analyze (so Freud's or Lacan's writings are themselves organized by the processes of repression, condensation, and displacement that they theorize); and
3. questioned the complicity of psychoanalysis with a logocentrism that believes in originary principles or an ultimate reality (Derrida, 1987).

Deconstructive thinking in psychoanalysis may seek not the origin of a trauma but the stakes of a belief in origin (Caruth, 1996).

Feminism/Gender Studies/Queer Theory

Although feminists have often been suspicious of deconstruction as a typically male pastime of abstract and universalizing thought that in effect sought to deny, for example, the authority of women's experience (since the appeal to experience always conceals presuppositions), some strands of feminist thinking espouse a deconstruction of the opposition between men and women and a critique of essentialist notions of identity (Elam, 1994). As the translator of Derrida's *Of Grammatology* and an eminent feminist, Marxist and postcolonial critic, Gayatri Spivak has been a powerful voice articulating deconstruction with feminist and other concerns (Spivak, 1988). But the most prominent result of deconstruction has been the work of Judith Butler, who draws on Derrida and Foucault in her theorizing of gender and identity, challenging the claim that a feminist politics requires an identity for woman (for Butler, identity is the product or result rather than the source of action). Butler develops a 'performative' concept of gender and sexual identity, modeled on the way in which linguistic acts (such as promising) work to bring into being the entities (the promise) to which they refer. This perspective has been influential in the realm of gay and lesbian studies or 'queer theory,' as the academic avant-garde linked to movements of gay liberation has styled itself (Butler, 1990, 2004).

Deconstructivist Architecture

The impact of deconstruction has spread beyond the humanities and social sciences to the field of architecture, where deconstructive architecture has come to mean design that flaunts, often in a parodic way, the elements from which it is constructed. In 1985, the architect Bernard Tschumi invited Derrida to collaborate on the design of a section of the Parc de la Villette in Paris, a large park surrounding new museums and exhibition spaces, in which design theory was to be staged in various ways. In Tschumi's plan, a series of large red cube-shaped spaces, the follies, were to be located at specific points; each cube was to be transformed, through 'deviation' into a folly, an explosion or expenditure of structure: the superimposition of different autonomous and logical structures subverted the notion of totality, and the design not only rejected the relation to context by which architecture is often justified but, dislocating and deregulating meaning, it aimed, according to Tschumi, at an architecture that means nothing (Tschumi 1988).

In 1988, Philip Johnson organized an exhibition at the Museum of Modern Art in New York entitled 'Deconstructivist Architecture.' In this perspective, what makes architecture deconstructive is not any derivation from the deconstruction in philosophy but its ability to disturb our thinking about form. This architecture disturbs and subverts by uncovering the instabilities or dilemmas hidden in traditional form, exposing the unfamiliar hidden within the familiar (Johnson and Wigley, 1988).

Religion and Theology

Less surprising is the interaction of deconstruction and the thinking of religion. As a critique of metaphysics, and specifically of the metaphysics of presence or the logocentrism of Western culture, deconstruction seems a resolutely antitheological enterprise, a critique of the theological motifs and structures that continue to undergird our thinking. But this devotion to uncovering the cryptotheological structure of Western secular thought, especially philosophy, gives rise to the idea that deconstruction is a version of negative theology.

Some scholars highlight the role of the concept of the messianic in Derrida's thought; and seek to recover Derridean concepts for a theology, linking the motif of deferral to the waiting for the messiah that marks Christian eschatology and moving from the argument that deconstruction contains religions motifs and a critique of a triumphant secularizing reason to the conviction that in 'religion without religion' or 'the messianic without the messiah' deconstruction gives us not the impossibility of religion but a religion with deniability, religion without the flaws of actual religions (Caputo, 1997). But the distinction Derrida makes between the messianic and messianism is crucial, not a quibble: it is the difference between analyzing a structure of awaiting and deferral and believing in an actual messiah (Derrida, 2002a).

Discussions of deconstruction and religion seem divided between, on the one hand, those who want to bring religion to Derrida and deconstruction, show deconstruction to be, finally, religious in its structure and commitments, giving rise to an ethics that preserves what is most valuable in modern religious commitment, and, on the other hand, those who want to bring deconstruction to theology in order to make it more philosophically complex, sophisticated, and responsible (Taylor, 1982). Must deconstruction assume atheism in order to function or might it work within a theological context and help produce a theology that could 'escape' philosophy? A third approach to deconstruction and religion, using deconstruction

to critique religion and theology, would seem the most obvious, at least based on Derrida's early work, but it was generally absent from the literature until Hägglund's *Radical Atheism* (2008), which decisively shows that deconstruction is not based on any desire for transcendence but rather on the valuing of the mortal, the transient. Derrida's contribution to the book *Religion* that he edited with an Italian philosopher takes on not theology so much as religion itself, as a social and intellectual phenomenon, and shows that deconstruction does indeed have a critical vantage point on matters religious (Derrida and Vattimo, 1998).

Politics, Law, Ethics

What is the relation between deconstruction and politics? Bennington notes that because Derrida's work in philosophy is very radical, there has been an assumption that it should give rise to a politics or political philosophy that is equally radical, so Derrida can be faulted for not living up to the expectations of those for whom politics is the real (Bennington, 2000). While Derrida has taken a position on many political issues and controversies, this sort of commitment has not been satisfying to many, who expect a political theory that will change the world.

Derrida has written extensively immediate political issues, such as apartheid, immigration law, terrorism, the death penalty, and European integration, and about political theory in the broadest sense, approaching politics and democracy through the issues of friends and enemies (Derrida, 2005, 1997). *Specters of Marx* interrogates the legacy of Marxism and its importance for a post-Marxist world (Derrida, 1994). The American Declaration of Independence has been analyzed as exemplary of the violence of acts of foundation, in which performative and constative dimensions of language fail to coincide (Derrida, 2002b). Woven through Derrida's work is a reflection on democracy, deconstruction, and decision: something is a decision only if it cannot be programed but occurs in a situation of undecidability; it must interrupt determination that is nonetheless its condition of possibility. (Bennington, in Royle, 2000). And democracy, a structure based on counting – the counting of singularities – is a concept in the name of which we criticize every determination of democracy; it is in the name of a 'democracy to come' that we deconstruct any given concept of democracy.

There has been considerable investigation of the topic of deconstruction and politics, and of the way in which deconstructive thinking can be marshaled for diverse political ends (Bennington, 1994; Beardsworth, 1996). Scholars/activists have developed a post-Marxist Marxism inflected by deconstruction (Laclau and Mouffe, 1985); and American political scientists have brought the thinking of the paradoxes of difference and the deconstruction of hierarchical oppositions to the discourse of political science (Connolly, 1992; Corlett, 1989; Martin, 1992). One should also place under the rubric of deconstruction and politics much writing in postcolonial studies (Spivak, 1999; Young, 1990).

In the field of law the Critical Legal Studies movement, which has focused on conflicts between principles and counter-principles within the system of legal doctrine has many affinities with deconstruction: critiques of the oppositions such as public vs private, essence vs accident, substance vs as form that are fundamental to the realm of law, and demonstrations that legal doctrine and argument are attempts to paper over contradictions, which nonetheless reassert themselves (Kelman, 1997). Derrida's own writing in this field has something of a different cast: his 'Force of Law: the Mystical Foundations of Authority,' for instance, explores the inextricability of foundational violence and justice (Derrida, 2002a).

The question of justice has been an important one for deconstruction, and leads to debates about deconstruction and ethics. Since deconstruction has been associated with disrespect for established norms and traditions and embrace of a Nietzschean trajectory beyond good and evil, the last thing it might seem to provide is an ethics. If the idea of ethics, with the concepts of law, responsibility, duty, and decision, is derived from metaphysics, how could deconstruction not put these in question? But the very fact that one formulates this as a matter of necessity or obligation draws attention to the possibility of asking what drives deconstruction? What sort of necessity, obligation, or commitment, ethical or not, is at work here, in the drive to deconstruct or in the sense of the importance of attending to deconstructions that happen?

This is a matter of ethics: what sort of value or obligation impels or compels one's actions? In the case of deconstruction, the question of ethics goes to the heart of the method. What impels deconstruction; why bother with it? The answers given often involve the structure of obligation itself, as writers explore the nature of the demand that drives deconstruction, whether the desire for justice, respect for the otherness represented by the text, or obligation to the otherness of the other. Derrida himself had a longstanding engagement with the thought of the philosopher Emmanel Levinas, whom he saw as awakening us to a conception of an unlimited responsibility that exceeds and precedes our own freedom. If one of the oldest ethical injunctions is 'Do unto others as you would have them do unto you,' a modern version, in what is called the 'Ethics of Alterity,' is to respect the otherness of the other: do not presume that the other is like you and thus claim a posture of universality, as if your views and feelings had universal validity. The problem of relation between the singularity of the other and the generality or universality that any ethical proposition entails is unresolved, an ongoing problem that will continue to engage thought of a deconstructive variety, whether in the future it call itself deconstructive or something else.

A concrete ethical issue to which Derrida turned in later years is the relation between the human and the animal. The characterization of the animal as other – Aristotle and Descartes denied reason to animals – has long helped to define the human. What is the nature and the impact of the distinction between the human and the animal? How is this distinction made, on what grounds, and with what values? Pursuing such questions, deconstruction contributes to the burgeoning interdisciplinary field of Human/Animal Studies. After women's liberation and gay liberation, animal liberation seems a further step – or if not animal liberation, recognition that the human treatment of animals for our own convenience is difficult to defend. Some critiques of the human/animal opposition show commonalities and continuities. On the other hand, a powerful strain of recent theoretical work focuses on the

discontinuities, the radical otherness and inaccessibility of animals, whom we cannot presume to understand (especially once we move beyond dogs and horses). Stressing the role that notions of the animal have played in defining the human, this approach demands respect for the otherness of animals and accuses proponents of the first approach of anthropomorphizing, treating animals according to human models.

Derrida seeks to escape the alternatives of a projection that appropriates and an interruption that excludes. He nevertheless emphasizes both the difficulties of understanding the animal's point of view and the human-centered violence of grouping everything from ants to zebra's as instances of 'the animal.' What happens if we move beyond thinking of cute middle-sized mammals and consider insects or birds, for instance? Any attempt to give a single answer concerning the conceptual relation of the human to the animal seems grotesquely human-centered (Derrida, 2008). The effect of recent theory here is to begin exploring the difficulties of maintaining a firm barrier between human and other species and recognizing the irreducibly multiple and reconfigurable relations with animals.

In its diffusion in the humanities and social sciences, following its greatest moment of fame in the 1970s and 1980s, deconstruction in the broadest sense has become a critique of categories taken as natural and a drive to pursue the analysis of the logic of signification in a given area as far as one can, even if the result is disquieting – an exacerbation of questions or problems rather than their resolution. It has thus joined with other strands of postmodern and post-structuralist thinking to inspire suspicion of established categories and canons and skepticism about objectivity. Although opponents of deconstruction have often sought to link its critique of established values to an amoral nihilism, as a critique of scientistic pretensions in the humanities and social sciences (among other things) deconstruction has included a strong element of ethical reflection, particularly about the conditions of possibility of ethics or justice (Critchley, 1992).

Abstract

This article explains the relevance of reasoning for prediction and explanation, i.e., for abilities that are fundamental for human survival. Since humans are prone to mistakes in their reasoning, reasoning systems offer desirable support. Deductive reasoning systems operate on a model of reasoning that results from a number of abstractions applied to human reasoning. These abstractions concern the language, the inferential relationship, and the syntactic nature of inference. By way of these abstractions, other modes of reasoning such as inductive reasoning are also covered. Basic issues concerning research in deductive systems, their performance and applications, and the psychology of human reasoning, are summarized.

Reasoning is one of the fundamental capabilities associated with intelligence as manifested in humans. It is a mental activity by which we generate knowledge not available prior to the act of generation. Experience shows that knowledge generated by reasoning on the basis of already available knowledge enables humans

- To predict states of the world not experienced before and to act accordingly and
- To explain phenomena experienced in the world so that we can understand the reasons why they happened, and make them happen again or avoid them in the future.

Prediction and explanation, and their combination, are fundamental and characteristic ingredients of the human way of life. In consequence, this is the case for reasoning as well, thus demonstrating its fundamental importance.

Experience also shows that humans have a sense for the correctness of reasoning chains and also an understanding that correct reasoning chains do not result in arbitrary predictions or arbitrary explanations. Rather, there is a correlation between the correctness of the underlying chain of reasoning and its usefulness for predictions or explanations in the real world: only predictions and explanations based on correct reasoning chains turn out to be useful in general.

On the other hand, humans are prone to mistakes in their reasoning. In coping with this and other weaknesses lies the motivation for the mechanization of reasoning in the form of *reasoning systems*. They might assist our reasoning, point out mistakes in it, or generate a correct chain of reasoning in cases too complex to be coped with by humans.

This article describes the formal basis for reasoning systems, points out a number of issues of particular importance for the design of such systems, surveys their numerous applications, addresses the philosophy and psychology of reasoning, and offers some literature on the subject.

Abstractions

Reasoning takes place in human minds. The understanding of the processes in the brain involved in reasoning is still in an embryonic state. Therefore, the study of reasoning so far can only be carried out at a higher level of abstraction. For more than two millennia, this study has been carried out at the level of language, thus abstracting from the processes that engage many subsystems in the brain including, for instance, those involved in the mental imagery system (Kosslyn, 1995). Since natural language is still too complex as a basis for the study of reasoning, further abstractions have been used. These are discussed in the present section.

Formal Languages

Any spoken or written text in natural language involves numerous linguistic constructs that carry a variety of informational content. Since reasoning relates assertions, we may for present purposes abstract from most of these linguistic constructs and restrict our focus on propositions (in the sense of logic). "The sun is shining" is a simple example of such a propositional statement.

Because of the complexity, ambiguity, and redundancy of natural language constructs even after the restriction just made, we further abstract from such propositions by use of some formal language. This should be rich enough to be able to express all our propositional knowledge, but simple enough to be useful for the manipulations needed in modeling reasoning, and concise enough to avoid ambiguities and redundancies. There are a number of formal languages meeting these criteria. They differ in the level of abstraction taken for the representation of knowledge and in the emphasis given to the various concepts involved.

The language of *propositional logic* takes the highest level of abstraction by formalizing knowledge at the level of entire propositions. For instance, the statement "The sun is shining" is taken as an atomic element in the language, thus abstracting from its intrinsic structure altogether. In the formalism the statement may therefore be abbreviated by any propositional variable, say S. As seen in section Variants, Specializations and Extensions, it is amazing how far the modeling power of this relatively poor language can already lead us.

The language of *first-order logic* (FOL) is less abstract and hence much more expressive. In our example, it allows the

distinction between the subject "The sun" in the noun phrase from the property "is shining" expressed in the verb phrase (or predicate) as well as the modeling of their relationship in a functional way, e.g., as *is_shining*(*The_sun*). In this way, it lays emphasis on the functional, or - after the philosopher Gottlob Frege - Fregean, relationships among relations, properties, and objects. Many knowledge representation formalisms are first-order formalisms in disguise. Among those are the Aristotelian language, which emphasizes sets rather than functions, the language of description logics (Bader, 2003) emphasizing concepts, associative nets emphasizing the relationships among objects and concepts in a graphical representation, and so forth. So FOL is probably the most popular formal language for knowledge representation, especially in the context of reasoning systems.

Modal, transitional, and higher order languages including lambda calculus extend the expressiveness of first-order languages even further. For the purpose of this article we put the emphasis on FOL, which includes propositional logic as a special case. Most of our considerations generalize in some way to the other more general languages.

The Inferential Relationship

Reasoning takes place with a given body of knowledge, say K, already available. In the *predictive mode* of reasoning we want to determine what facts, say P, could be true in the future. Correct reasoning distinguishes between facts possible on the basis of K and those that are impossible. In other words, there is a relation that associates K and P in the positive case. Following Frege this relation is formally denoted by $\models$. That is, $K \models P$ is short for expressing that P is a correct reasoning prediction on the basis of K. In the predictive mode of reasoning, we thus want to determine P such that $K \models P$ holds, or test for a given P whether it holds.

Human reasoning is mostly done with respect to chronological processes and to a significant extent also concerns knowledge about actions and changes taking place in time. On the other hand, a large part of the inferential relation $\models$ is so to speak "timeless". To simplify further, most logical studies have abstracted from the issues concerning time and change. Only in the last few decades have those issues become of great interest within *Intellectics*, the field studying intelligent behavior and systems within Artificial Intelligence (AI), Cognitive Science, and Neuroscience. The result of those recent studies is that the timeless part of $\models$ is already expressive enough to model the part involving time as well and thus the entire relation $\models$. Insofar this abstraction from time is without restriction of generality. Under this abstraction the predictive mode of reasoning is called the *deductive mode* of reasoning. Because of what we just said, deductive reasoning is timeless reasoning at the surface, but may model general predictive reasoning.

In the *explanatory* mode of reasoning based on K, we start with some observation O and basically look for some explanation E so that $K,E \models O$. This mode of reasoning is called *abductive* or *inductive* depending on the circumstances concerning O and E. Since $\models$ is a relation, the difference to deductive reasoning is minor; instead of the second argument of the relation $\models$ here just (part of) the first one is to be determined. The relationship is even closer. In abductive or inductive reasoning, we employ additional metaknowledge, say M, which guides the process of generalizing from given observations. Taking this into account, inductive reasoning actually boils down exactly to deductive reasoning, namely, in the form $K,M,O \models E$ whereby now the explanation E is deduced from K and O guided by M in some way.

In summary, all prevailing modes of human reasoning may actually be regarded as deductive reasoning. This explains why deductive reasoning systems have such a great importance for modeling inference in all its generality.

Syntactic Inference

The fundamental observation already made more than two thousand years ago by Aristotle and his predecessors is that reasoning (apart from psychological considerations) is a matter of form rather than of content. This became apparent once knowledge was represented in a formalized way. The knowledge "apes are mammals", in the sense of "whenever the property of being an ape holds then also the mammal property holds", or $A \rightarrow M$, and "mammals have hairs", $M \rightarrow H$, allows us to conclude that "apes have hairs", $A \rightarrow H$. The inference is valid independently of the meaning of the words apes, mammals, and hairs, or of the symbols A, M, and H for that matter. Rather it is exclusively the form of the knowledge that sanctions the validity of such an inference. This fundamental property of reasoning enables machines, which to date are ignorant of the meaning of words or symbols, to perform correct inferences.

The example demonstrates a fundamental rule of inference: $A \rightarrow M$ and $M \rightarrow H$ imply $A \rightarrow H$. It is called (a restricted form of) *resolution* or (a slightly generalized form of) *modus ponens*. As we see, it produces new knowledge ($A \rightarrow H$) by eliminating the intermediate *atom* M; thus, the rule may also be seen as implementing a form of transitive closure.

In order to program computers to search for chains of inferences we first need rules of inference such as the one just discussed in addition to the formal languages mentioned before. The combination of a formal language along with a set of rules is called a (formal or logical) *calculus*. If F is some *formula*, i.e., a propositional expression in the formal language under consideration, viz. FOL according to our convention, and G is a formula obtained from F by applying the rules of the calculus, then we write $F \vdash G$. Since $\vdash$ is dependent on the calculus, say c – which, as in the case of formal languages, can be chosen from a great variety of alternatives – we should rather write $\vdash_c$ but omit the index whenever the calculus is clear from the context. We want to design calculi in such a way that $F \vdash G$ holds if, and only if, (shortly, *iff*) $F \models G$, in which case we speak of *correct* (if) and *complete* (only if) calculi. From now on we assume that the rules are chosen such that the resulting calculi are always correct and complete.

We go one step further in the abstraction process described in this entire section. According to the well-known deduction theorem, it holds that $F \vdash G$ *iff* $\vdash F \rightarrow G$. By (iteratively) applying this theorem, we can always achieve that there are no formulas to the left of $\vdash$. Most deductive systems in use are therefore systems that test whether, for some given calculus and some given formula F, it holds that $\vdash F$ (establishing an affirmative proof), or dually, that $\vdash \neg F \equiv$ *false* signaling a contradiction (proof by contradiction).

Let us illustrate the result of this abstraction process by our apes–mammal–hair example. The example asserts that $A \rightarrow M$ and $M \rightarrow H$ implies $A \rightarrow H$. Using the logical symbol $\wedge$ instead of "and" the assertion reads $(A \rightarrow M) \wedge (M \rightarrow H) \vdash (A \rightarrow H)$. Applying the deduction theorem yields $\vdash (A \rightarrow M) \wedge (M \rightarrow H) \rightarrow (A \rightarrow H)$. The formula to the right of $\vdash$ is an example for what was briefly denoted by F above. It could be presented as input to a deductive system, which would easily verify that the formula is valid. If the system works by contradiction, the presented formula would rather be $\neg[(A \rightarrow M) \wedge (M \rightarrow H) \rightarrow (A \rightarrow H)]$.

The field in which such systems are developed, studied, and applied is called *automated deduction* (AD) or *automated reasoning* (AR). It has applications in any field where reasoning of any kind is relevant, which actually is most of science, or most of human endeavors for that matter. Since AD's first application was to mathematics, the field is also known as *automated theorem proving* (ATP).

Issues in Automated Deduction

There are numerous deductive systems that differ in the formal languages or the set of rules making up the underlying calculus. Further distinctions are the strategies used for the proof search, the data structures used for the representation of the formal constructs involved, the programming language used for the code, and so forth. Some of these issues are discussed in the present section.

Clausal Form, Resolution, Tableaux, and Connection Method

A very popular language is a version of the language of FOL, called *clause form*. It uses sets of clauses. A clause is a disjunction of literals. A literal is an atom or its negation. An atom is the simplest propositional construct such as *is_shining(The_sun)* or the A in the ape example, i.e., without involving any logical connections.

Any formula of FOL can be transformed into clause form by a straightforward algorithm based on well-known laws of propositional logic (and techniques discussed in the next section); the algorithm is not explained here in detail. Its application to our formula $\neg[(A \rightarrow M) \wedge (M \rightarrow H) \rightarrow (A \rightarrow H)]$ leads to the following set of four clauses: $\{(\neg A \vee M), (\neg M \vee H), A, \neg H\}$. The meaning of the comma separating the clauses in the set may be viewed as that of a conjunction $\wedge$.

A correct and complete calculus based on clause sets is given by (essentially) the single rule of *resolution*, which was mentioned already in section Syntactic inference. In clause form, it operates on two selected clauses in the given clause set; the two clauses must be of the form $1 \vee A \vee 2$ and $3 \vee \neg A \vee 4$, where the numbers stand for arbitrary, possibly empty clausal parts. The pair $\{A, \neg A\}$ is called complementary, or a *connection*. The result of a resolution step then is $1 \vee 2 \vee 3 \vee 4$, called the resolvent. For example, the resolvent of the first two clauses $\neg A \vee M$ and $\neg M \vee H$ in our example is $\neg A \vee H$. The resolvent (of each resolution step in the derivation) is added to the set of clauses. If the next resolution step selects this last resolvent and the clause A, then the newly added resolvent thereof is H. If this resolvent again is selected together with the clause $\neg H$ then the empty clause results as resolvent. The empty clause represents *false*. Its occurrence in this process is the criterion for success. Once this criterion is fulfilled it is guaranteed that the original formula, from which the deduction process started off, is indeed valid.

A deductive system based on resolution works as a saturation process. It takes the given clause set, and iteratively applies resolution until the empty clause is obtained. The advantage of this type of system is the simplicity of the data structures involved (clause sets) and of the operations performed at each iteration (resolution). The problem is that without additional constraints the system produces relevant and irrelevant intermediate results alike, and for hard problems often is drowned in up to billions of generated clauses. An irrelevant intermediate result in our earlier example might be that "apes have eyes" on the basis of the additional knowledge that "mammals have eyes" when our only interest is in the question about hairs. *Strategies* (like the so-called set-of-support strategy) and reduction rules to some extent help to reduce the amount of irrelevant clauses generated.

An alternative to this *saturation-based* approach are *goal-oriented* tableaux-based deductive systems. Human proofs, i.e., chains of inferences, may be regarded as treelike structures, or (closed) *tableaux*, which in each branch start out from an obviously valid fact. The basic data structure of tableaux-based systems is a (not necessarily closed) tableau. Starting with the tableau consisting of the (denial of the) given formula, the tableau is extended at each iteration with the goal of closing it. The data structure (tableau) and the operations (extension of tableau) are more complicated than those in the saturation-based systems, which complicates the system development. But the approach lends itself to a more goal-oriented fine-tuning of the search for the final proof and can therefore avoid some of the redundancy involved in resolution systems without extra efforts.

Systems based on the *connection method* may be regarded as a compactly coded form of tableaux systems. In this method, all information coded by a tableau is attached in an extremely condensed form to the parts of the given formula as structural information. Starting with an initial structure of this kind, only the structure is modified at each iteration until a certain final structure signaling validity of the formula is reached; in contrast to the previous kinds of methods, the formula itself is not changed at all in the process. As we saw already in the resolution method, connections (i.e., complementary pairs of literals) play a fundamental role in proofs. In the connection method they guide the proof search. In the final structure just mentioned, a so-called spanning set of connections for the formula is identified, which characterizes the validity of the formula. For our example, this structure consisting of three spanning connections is illustrated in the following picture.

Research in AD pursues all three kinds of approaches, with the focus in each case being on eliminating redundancy. This can be achieved in various ways. One way consists of refined

calculi in terms of the rule sets used. For instance, the application of resolution may be restricted in many ways without sacrificing completeness (e.g., linear resolution). This also includes the application of reduction rules (e.g., subsumption). Another way to reduce redundancy is by applying various strategies that guide the rules application. A third is by performing several small steps as a single global step (e.g., hyperresolution), which again narrows the search space. A fourth involves global steps sanctioned by theories involved (such as equality theory, see section Variants, specializations and extensions). Finally, ever improved software engineering techniques and faster machines contribute to a continuous enhancement of system performance. On top of all, heuristics try to achieve success faster by sacrificing completeness of the method.

First-Order Features

For simplicity, the introduction of some AD methods in the previous subsection has glossed over a number of details. While speaking of FOL, no first-order features beyond the propositional ones were actually taken into account. For instance, the apes example actually talks about objects with certain properties so that its first-order formula would rather read $\forall x\ [(Ax \rightarrow Mx) \wedge (Mx \rightarrow Hx) \rightarrow (Ax \rightarrow Hx)]$. In order to save parentheses, the atoms like Ax are short for the functional form $A(x)$ reading "x is an ape". The statement is asserted for all objects x, formally expressed by the universal quantifier $\forall x$. In addition, FOL features an existential quantifier as in the sentence "any human has a mother", formally $\forall x \exists y\ (Hx \rightarrow Myx)$, whereby Hx is short for "x is human" and Myx abbreviates "y *is* mother of x".

As these examples illustrate, atoms in FOL have an internal structure. It consists of a predicate symbol like M and a certain number of arguments, two in the case of M. The arguments can be variables like x or constants like "*The_sun*", or shortly s. They may even involve functions like "the color of s", or shortly $c(s)$. Altogether we speak of terms serving as arguments.

The occurrence of quantifiers in the formulas to be deduced affects the transformation algorithm into clause form. By a technique called *skolemization* existential quantifiers are eliminated and then all-quantifiers ignored by default. As a result, a set of clauses looks as before except for the more complicated atoms involved. For instance, the apes example would now look like $\{(\neg Ax \vee Mx), (\neg Mx \vee Hx), Ax, \neg Hx\}$.

Connections like $\{A, \neg A\}$, because of the richer structure of atoms, may now become more complicated such as e.g., $\{A(x,f(z)), \neg A(b,y)\}$. Whether or not such a connection can be made complementary and thus will contribute to a proof is subject to a further technique called *unification*, which assigns values (or rather terms) to the variables involved. In the present example, x would be assigned the term b, and similarly y the term $f(z)$; in short, this substitution may be written as $\{x\backslash b, y\backslash f(z)\}$, resulting in the complementary connection $\{A(b,f(z)), \neg A(b,f(z))\}$.

The three types of methods introduced in the previous subsection engage unification in some way, which will not be described here in detail. Resolution, enhanced by unification, allows the elimination of intermediate literals (i.e., connections) even if they are not exactly identical but can be made identical by replacing variables in the atoms by terms as just described. For instance, the resolvent of the first two clauses in the apes example now is $\neg Ax \vee Hx$ and similarly for the two other steps. Except for the additional unification the proof proceeds as before, resulting in the empty clause. In general, the resolution method requires an additional rule of inference, viz. factoring, by which two different literals in a clause by way of unification are factored into a single one.

The proof of our running example in the connection method is unchanged as well:

$$(Ax \rightarrow Mx) \wedge (Mx \rightarrow Hx) \rightarrow (Ax \rightarrow Hx)$$

Note that each connection corresponds to a respective step in the resolution derivation described above. For comparison, recall that resolution in each step adds a new clause to the clause set and thus with it new connections. In contrast, the connection method is concerned exclusively with the connections present in the formula to be proved, although these connections by the nature of FOL may be required in different instances. This allows a more focused search, guided by the structure of the formula in a connection-oriented way. In addition, in the connection method no transformation into clause form is required (Otten, 2011). This is an advantage since this transformation in general introduces redundancy thus increasing the search space. On the contrary, the given formula may even be reduced by factoring, making it more nonnormal, possibly resulting in (much) shorter proofs and less proof search (Bibel, 2006).

In section Syntactic inference we have made the distinction between affirmative proofs and proofs by contradiction. Technically, there is no argument for one or the other form. Any method can be formalized either way without affecting performance. In addition, there is an "affirmative" clause form defined similarly to the one introduced in section Clausal form, resolution, tableaux, and connection method. Resolution by historical accident is usually presented as a proof-by-contradiction method, while the connection method is usually affirmative. The tableaux method is used both ways.

Variants, Specializations, and Extensions

FOL is a rather expressive formalism in which, for instance, all of mathematics as well as more or less all of science can be represented. Typically, deductive tasks arise within a given theory. For instance, if the task F involves an equation then the theory has to contain the equality axioms, say $T_=$. These are, for instance, the axioms of reflexivity and substitutivity (for functions and predicates). The formula to be proved thus has the form $T_= \rightarrow F$, and it is straightforward for deductive systems to attempt a proof for such a formula.

In comparison with the human way to solve equations, however, this approach involving the equality axioms seems pretty awkward. Rather, humans proceed in such cases by substituting terms by equal terms until the equality becomes an identity. This is the motivation for treating equality in rather special ways also in deductive systems. For instance, resolution has a special rule called paramodulation by which equal terms may be substituted without any reference to axioms. Similar

techniques have been developed for the tableaux and the connection method. In fact, there is an extensive research area known as "term rewriting", in which efficient algorithms for treating equality theories have been developed. Appropriate techniques are also available for other special mathematical tools (like mathematical induction) and theories.

The programming language PROLOG (Clocksin and Mellish, 2003) is a restricted FOL language enriched by control features. It restricts the formulas to so-called Horn clauses, which in the contradiction mode means that there is at most one negative literal in each clause. A PROLOG clause is written $A_0 := A_1, A_2, \ldots, A_m$, with the left side of := called the head and the right the body of the clause. For instance, the clause $Ax \rightarrow Mx$ from the apes example here reads $Mx := Ax$, which by comparison of the two versions shows that := can be interpreted as an implication from right to left. In the case $m = 0$ (i.e., no body) the sign := is deleted. A PROLOG program is a set of PROLOG clauses. A clause with no negative literal is written ?– $A_1, A_2, \ldots, A_m$. It is called a query. Except for these superficial syntactic differences a PROLOG system behaves much like a deductive system based on the methods discussed before. One exception is the possibility of allowing negated atoms *not* A_{m+1} in the clause body, which are treated with a special technique called "negation as failure". In addition, with respect to applications in AI the semantics of a PROLOG program differs from that of a corresponding classical formula. The control features allow the programmer to overrule the system's built-in control.

In section Formal languages we already mentioned description logic (DL) as a first-order formalism in disguise. More precisely, DL is actually a family of formal knowledge representation languages which, due to certain restrictions, feature more efficient deductive proof procedures than full FOL (mostly even decision procedures). It models concepts, roles and individuals, and their relationships. For instance, *woman* = *adult* $\sqcap$ *gender*:*female* might be a definitional statement of the concept "woman" in DL. In FOL such a concept is represented as a predicate (like in *Woman*(*mary*)). This syntactic difference is irrelevant from an efficiency point of view; the decisive difference lies in the restrictions imposed on the operations of the language, which lead to less expressiveness of the language but to a higher efficiency of the resulting deductive systems.

Another restricted form of FOL is the formalism of syllogisms, originally invented by Aristotle. It features judgments of the form *all apes are mammals*, or *AaM*, *at least one ape is old*, or *AiO*, and so forth. Along with judgments of these kinds there are inference rules. For instance, the apes–mammals–hair example is an instance of what is known as the valid inference Barbara: *AaM*, *MaH* → *AaH*. The traditional names of these rules are chosen for mnemotechnical reasons: the three *a*'s in the word "Barbara" remind of the three *a*'s in the rule. In Brüning (1996) a strict formalism based on syllogisms has been developed but not yet been realized in a running system.

So far we have discussed restricted forms of FOL. Conversely, there are numerous extensions of FOL, too many to discuss here in any detail. We just mention the great variety of modal and temporal logics that feature additional logical operators (e.g., the necessity operator $\Box$ or the possibility operator $\Diamond$) beyond those of FOL along with corresponding rules of inference. Higher order logic (HOL) is the most powerful extension beyond FOL. It allows the quantification over functions and predicates according to familiar practice, e.g., in mathematics. A formalism for representing HOL is type theory. For all these extensions there are deductive formalisms and systems, analogous to those of FOL, yet more complicated.

All formalisms discussed above test the validity of formulas, i.e., their truth under *any* interpretation. Often it is already sufficient to test the given formula for its satisfiability, i.e., its truth under *one* particular interpretation rather than under all interpretations. This semantic approach has found many applications especially for the restricted language of propositional logic. The satisfiability of propositional formulas is known as the problem class SAT. For instance, the apes–mammal–hair example formula $(A \rightarrow M) \wedge (M \rightarrow H) \rightarrow (A \rightarrow H)$ will turn out true if all propositional variables A, M, H are assigned the value *true* (and in fact under any assignment due to the formula's validity).

There are extremely powerful systems for SAT problems and variants of these, solving problems that may involve millions of propositional variables. One of the popular techniques uses binary decision diagrams, or BDDs (Bryant, 1992). This formalism treats propositional formulas, restricted to the operators conjunction, disjunction, and negation, in a functional way. Here conjunction is written like a product, disjunction as sum, and negation with a bar, e.g., $f(A,M,H) = [A\bar{M} + M\bar{H} + \bar{A} + H] + \bar{A} + H]$ for the formula after elimination of → according to the rules of propositional logic. The efficiency of BDDs is achieved basically by a reduction in the formula by factoring identical subformulas and by choosing a special order of the variables in the formula.

Answer set programming (Gelfond, 2008), or ASP, is a form of declarative programming similar to PROLOG, but with a different semantics and solution technique. The language uses PROLOG clauses with a number of additional features. The semantics is based on so-called stable models. The solution technique includes a grounder and a solver. The grounder in essence transforms the problem into a propositional formula; the solver is something like a SAT solver. Among the additional features are several language extensions like integrity constraints, choice rules, cardinality and weight constraints, and so forth. These language features render ASP a rather expressive representational formalism. ASP is extremely powerful for solving difficult search problems. Due to its declarative nature, it offers a great advantage in comparison to programming such problems in a conventional programming language.

Complexity, Systems, and Performance

From a theoretical point of view, AD is one of the hard problems in computer science. SAT solving, i.e., semantic propositional reasoning, is already NP-complete, which (for the state of art) essentially means no procedure can solve all propositional formulas efficiently, even if the formulas are comparably small. First-order reasoning is even more difficult, since FOL is undecidable: there is no procedure that can decide for all formulas if they are valid or not.

Nevertheless, research in AD has produced a variety of reasoning techniques that can solve most reasoning problems very efficiently. Propositional reasoning techniques like conflict analysis, clause learning, backjumping, adaptive branching, random restarts, and problem reductions have increased the

performance of SAT solvers by many orders of magnitude, which makes it possible to apply them to formulas with millions of clauses and variables. In first-order reasoning, indexing techniques, efficient data structures, and search heuristics have led to efficient proof systems capable of dealing with complex reasoning tasks.

In the past years, benchmark collections have made it possible to evaluate the performance of AD systems, while annual system competitions in SAT solving (The International SAT Competitions Web page) and first-order theorem proving (The CADE ATP System) have resulted in significant improvements. Currently, the best SAT solvers are *3S*, *ppfolio*, and the ASP system *clasp*, while systems like *Vampire*, *Waldmeister*, *Spass*, *E*, and *leanCoP* are the most successful first-order theorem provers. However, the winners of these competitions keep changing, since the development of reasoning techniques makes previously unknown systems even more efficient than the winners of the past years.

Artificial Neural Systems

Human reasoning takes place in brains. The mechanisms occurring in brains are modeled by connectionist systems. So the question naturally arises whether reasoning could be modeled by a connectionist, also termed artificial neural, system. Since we do not yet know how the brain realizes reasoning, such a system could be a very first step toward understanding the brain's processes in reasoning.

Several neural systems have been developed that perform deductive (and abductive and other kinds of) inferences, mostly for propositional logic. The so-called CORE method ("Connectionist mOdel generation using Recurrent networks with feedforward core") achieves such inferences semantically by generating or approximating a (possibly least) model of the premises under which a conclusion can be drawn. In the propositional case, the model can iteratively be computed by a three-layer feed-forward core (i.e., connectionist network) until a stable state is reached. Thereby, the output nodes of the network are recurrently connected back to the input nodes to allow for the iterations. With a number of additional ideas this method has been generalized to the first-order case (Baader et al., 2008). Here, the model can only be approximated, however, with arbitrary precision.

The CORE method bridges the gap between the discrete world of logic programs and the continuous world of neural networks. It integrates distinct functions such as transforming programs (as background knowledge) into networks, learning and optimizing networks, generating or approximating models from networks, drawing inferences by way of the models, and extracting a logic program from a learned or optimized network.

Applications

As pointed out in the introduction, reasoning is a fundamental human capability. Therefore, it pervades many of our activities. In consequence, reasoning systems have numerous and widely varied applications. Some of these are briefly discussed in the present section.

Mathematical Theorem Proving

Originally, mathematics has been the primary field of application for AD. Deductive systems have been applied to virtually all subdisciplines in mathematics, and tens of thousands of theorems have been proved automatically. Automated theorem provers have found new proofs for known theorems as well as proofs of unsolved mathematical problems and conjectures that had never been proved by humans before.

For instance, in 1996, a system called Otter/EQP solved the so-called Robbins problem, which had been open for more than 60 years. The machine-generated proof consists of only 13 equations and can therefore be checked easily by human mathematicians. Finding this proof, however, took more than 7 days of intense machine computation, as several thousand equations had to be generated and combined in order to construct the proof (Kolata, 1996, McCune, 1997).

Another famous example is the proof of the four color theorem, which has been conjectured in 1852 and was the first theorem to be proved by a computer in 1976 (Appel and Haken, 1977). To prove the theorem, a special-purpose computer program had to analyze 1936 different maps. This resulted in a proof that is infeasible for a human to check by hand and is not accepted as a convincing proof by some mathematicians. In 2005, the theorem could be proved with the help of a general purpose theorem prover Coq (Gonthier, 2008). Although even this proof cannot be checked without the help of a computer, it was sufficient to dispel remaining doubt about the validity of the four color theorem.

Hardware and Software Verification

One of the most important applications of AD techniques today is the verification of software and hardware. In the early 1990s, major flaws in hardware design such as the Pentium FDIV bug resulted in hundreds of millions of dollars of damages and caused the industry to look for tools that could validate the design of complex hardware circuits. At the same time, new techniques for eliminating redundancy in propositional reasoning led to significant efficiency improvements, which permitted the use of model checkers and SAT solvers in large-scale applications involving millions of components (Clarke et al., 1999). As a result, model checkers were adopted as the standard technique to verify the design of computer chips before they go into production.

While the verification of hardware involves the analysis of a huge number of possible states, the problem is finite and can therefore be represented in propositional logic. In contrast, software can assume infinitely many different states, which makes software verification much more complex. For specific types of software such as compilers, state-based systems like communication and security protocols, and some commercial applications, it has been demonstrated that automated proof systems and software model checkers are capable of constructing proofs that guarantee the software's validity. But in general these systems do not scale well enough to deal with the complex formulas that are needed for the description of real-world software.

Software and Hardware Synthesis

An alternative approach to software validity is based on the idea that programs and proofs of their correctness should be developed simultaneously instead of verifying software after it has been created. Program synthesis aims at using AD to develop "correct-by-design" software from descriptive specifications. Ideally, a programmer would focus on designing a precise formal specification of a given problem and then call a deductive system to generate the actual implementation. The programming language PROLOG basically works as such a deductive system. However, as a programming language, it also contains nondeclarative control mechanisms and is only a first step toward "programming in logic".

Systems that synthesize programs from descriptive specifications involve strong deductive components to ensure the correctness of the generated program. The systems KIDS and Specware/Isabelle have been used in the automated construction of commercial software and scheduling algorithms that are not only correct by design but also significantly more efficient than hand-crafted versions (Smith, 1991, Smith and Parra, 1993). The higher order theorem prover Nuprl has been used for the semiautomated development and optimization of distributed software with more than 50 000 lines of code (Liu et al., 1999). A key to the success of these systems was the fact that the deductive components were guided by strategies that incorporate knowledge about algorithmic structures and efficiency optimizations.

In hardware design, the standard procedure consists of describing the behavior of circuits in a hardware description language at logic level followed by extensive verification and logic synthesis, a process of turning the circuit descriptions into a design implementation in terms of logic gates. This procedure consumes significant amounts of time and needs a lot of effort. While the idea of synthesizing hardware circuits from logical specifications has been proposed several decades ago, it was deemed impractical because of its high computational complexity. Recent developments (Bloem, 2007), however, have made it applicable to realistic examples, and it is expected that hardware synthesis based on AD will eventually be used in industrial applications.

Knowledge Systems

Reasoning generates new knowledge from given knowledge. Hence, it is an essential feature in any system that incorporates explicitly represented knowledge. Such a system is variably called knowledge system, knowledge-based system, expert system, semantic web, ontologies, and so forth. In the CYC system an entire encyclopedia of knowledge is encoded in this way. Numerous special systems encode knowledge of specific disciplines, allow the manipulation of such knowledge in a deductive way, or can answer questions in complex scenarios (Harmelen et al., 2007). For instance, in 2011, the system WATSON outperformed the two best human players in the US quiz show Jeopardy. Similarly, the Apple iPhone 4S features a system Siri, which understands and answers queries in spoken natural language, not least because of deductive mechanisms. These are just three examples out of tens of thousands of such systems. In the emerging technology of real-world awareness, coping with the masses of information will only be possible if inductive systems will extract knowledge from the data.

Philosophy and Psychology of Reasoning

As seen in the previous section, deductive systems are becoming a part of daily life. We want them to behave rationally in the human sense. Hence, we need to understand human rationality and reasoning in the first place, a goal pursued for more than two thousand years first in philosophy, then in psychology, and more recently in intellectics. In this section, we discuss philosophical and psychological aspects of reasoning.

Can Reasoning Be Mechanized?

Logic and the study of deductive reasoning was a primary topic in philosophy for more than two thousand years (for an exposition of this history see Kneale and Kneale, 1984). Since the nineteenth century, it transformed more and more into a mathematical subject, whereas in the past 60 years it has become a major topic in AI. Therefore, today the major contributions to the subject do not originate in philosophy anymore – with one exception: many philosophers have tried in thousands of papers to argue in favor of the thesis that the mechanization of reasoning has strict limitations and will never be able to reach the human level of performance. Herbert Dreyfuβ, John R. Lucas, Roger Penrose, and John Rogers Searle are some of the philosophical spokesmen in this debate. The debate is a fruitless one, and the arguments in favor of the thesis have proved faulty. One of the papers that have defeated the thesis is LaForte (1998). Although we indeed do not know in detail how the brain realizes our thinking, the computationalism underlying intellectics at present is the best available scientific approach.

Psychology of Reasoning

In many respects, the best available deductive reasoning system is still the human mind. Psychological studies and thus our understanding of (the phenomenological part of) human reasoning can therefore enhance the design of artificial deductive systems (Evans, 1970). The key idea is that humans – in contrast to machines – construct internal representations of the state of affairs described by a logical argument in order to understand it. These "mental models" are similar to the models that people use to perceive the world, but rudimentary and incomplete. Experimental evidence seems to indicate that human deduction depends less on laws of inference but rather on a search for alternative models of the premises that could refute a given conclusion and that a conclusion is accepted as long as there is no refutation for it.

Most humans, for instance, appear to read an implication as bi-implication, or equivalence, and draw conclusions like the following.

- *If John is in New York then Cathy is in New York too.*
- *John is not in New York.*
- *Therefore Cathy isn't in New York either.*

which obviously is not a correct deduction from the point of view of classical logic like FOL.

Negation is even more difficult. The sentence

- *John wouldn't have been in New York if Cathy hadn't been there.*

is logically equivalent to the first one above but is perceived differently.

The theory of mental models aims at capturing the difference between human and formal reasoning. In this theory, the process of deductions depends on a semantic procedure that constructs an internal representation of what has been stated, tries to draw possible conclusions by formulating a more elaborate model based on that representation, and attempts to find a countermodel for that conclusion. If no such countermodel is found, the conclusion is considered valid and the process continues by proposing further conclusions and trying to refute them.

On this basis, cognitive scientists and psychologists have formulated a comprehensive theory of human inference that explains propositional, quantificational, and relational reasoning (Johnson-Laird and Byrne, 1991, Johnson-Laird, 1999). This theory has been used as a foundation for implementing reasoners that appear to be a more appropriate model of the human intellect. There are also theories that view human deduction as a process based on factual knowledge (Anderson, 1993, Newell, 1990) or on formal rules of inference (Rips, 1994) similar to those used in AD. Evidence from a wide range of studies seems to indicate that the theory of mental models provides the most appropriate representation of the mechanisms underlying human deduction. However, in contrast to other areas in psychology such as image processing (Kosslyn, 1995) or "system 1 mental operations" (Kahneman, 2011), reasoning (a system 2 operation) is still poorly understood.

Fitting, 1990 is an excellent textbook on propositional and first-order logic. Bibel, 1993 is a special textbook on all aspects of deductive methods and systems. Bibel and Schmitt, 1998 is a reader covering all modern deductive techniques, a number of very successful systems, and several important applications. Gabbay et al., 1991 is a handbook that includes deductive reasoning systems and other topics. Robinson and Voronkov, 2001 is a handbook covering just deductive methods, techniques, and systems. Plaisted, 2009 is an encyclopedia article similar to the present one. Ongoing research is reported in the *Journal of Automated Reasoning* (Kluwer Academic Publishers) and in the proceedings volumes (published by Springer Verlag) of the International Conferences on Automated Deduction as well as in other journals and conferences.

EDITOR IN CHIEF BIOGRAPHY

James D. Wright received his bachelor's degree in philosophy from Purdue University in 1969, a master's degree in sociology from the University of Wisconsin in 1970, and his PhD in sociology from Wisconsin in 1973. His first academic appointment was at the University of Massachusetts, Amherst, where he was promoted to Associate Professor in 1976 and to Full Professor in 1979. Most of his 15 years at Massachusetts were spent as Director, Associate Director, or Director of Research in the Social and Demographic Institute.

Wright left Massachusetts for Tulane University in New Orleans in 1988 where he served as the Charles and Leo Favrot Professor of Human Relations in Tulane's Department of Sociology. He also enjoyed a courtesy appointment in the Tulane School of Public Health, Department of Biostatistics and Epidemiology. He left Tulane in 2001 to become the Provost's Distinguished Research Professor of Sociology at the University of Central Florida. In 2003, he was named as the Director of the University's Institute for Social and Behavioral Sciences and in 2013, was designated as a UCF Pegasus Professor, the University's highest faculty honor.

Wright was the Editor in Chief of the scholarly journal *Social Science Research* from 1978 until 2014. His previous editing experience also includes a 20-year stint as editor of the Aldine de Gruyter book series *Social Institutions and Social Change*, two editions of the *Handbook of Survey Research* (Academic Press, 1983; Emerald Publishing, 2010), and service on the editorial boards of numerous journals. He is the author of 21 books and scholarly monographs on topics ranging from homelessness to research methods to NASCAR, and he has published more than 300 journal articles, book chapters, reviews, essays, and polemics. Wright lives with his wife Christine Stewart and their multiple dogs and cats in Winter Springs, Florida, where in his spare time he likes to cook fancy meals for large crowds.

PREFACE TO THE FIRST EDITION

Large and ambitious works such as the present Encyclopedia depend on countless instances of input, cooperation, and contextual support. Therefore, the editors in chief would like to express their gratitude to several institutions and individuals. Our most general thanks go to our respective home institutions, the Center for Advanced Study in the Behavioral Sciences, Stanford, and the Max Planck Institute for Human Development, Berlin. We are certain that without the effective infrastructures of these institutions and the rich collegial networks and intellectual climate they provide, implementing this Encyclopedia in such a short amount of time would not have been possible. In this context, we also need to mention that due to the administrative budgets provided to the editors in chief by the publisher, the financial strains on our home institutions were minimal. Such a situation may be a rarity in the modern world of scientific publishing where publishers often press scholars and institutions into taking on larger and larger shares of the publication enterprise.

Aside from the more than 4000 authors, our deepest thanks goes to the editors of the 39 sections, to whom we delegated many decisions at various stages, who were primarily responsible for developing the lists of articles and authors, and who stood as the main gatekeepers of scientific quality for the entries in their sections. As a group, the section editors displayed remarkable energy, intelligence, and tolerance for the inevitable frustrations of tending large numbers of authors over a long period of time. Because of the brevity of the acknowledgment of the main editorial coproducers here, we alert the reader to the list published as part of the front matter and the description of their extensive work we offer in the Introduction. We would also like to mention that one of our highly esteemed section editors, Franz Weinert, died unexpectedly during the last phases of his editorial work. For people who had the pleasure of knowing Franz Weinert, it comes as no surprise that he completed his editorial duties without ever complaining about the difficult health conditions he was facing. He was a gentleman and a distinguished scholar.

The International Advisors also gave wise counsel on several designated occasions, and a number of these scholars represented on the International Advisory Board took more initiative — always helpful — than we had originally asked. The International Advisory Board was particularly helpful in the process of choosing section editors. Some of its members assisted us ably as we attempted to make the Encyclopedia as international as possible and also in dealing with special problems that are part of a large project with close timelines. Thus, we remember a few occasions where members of the International Advisory Board helped us with their substantive and social competence to deal with matters of editorial disagreements. Because of the overall quality, collaborative spirit, and professional responsibility of our section editors, these events were rare indeed, but dealing with them required masterful and accelerated input. We appreciate the collegiality that members of the Board displayed when called upon in these special circumstances.

In addition, and as described in the Introduction, there was a host of esteemed colleagues who gave us advice on numerous questions such as author and editor selection, organizational matters, topics for entries, content and quality of selected articles, substantive and methodological niches to be covered, as well as last-minute author replacements. The number of such individuals is large indeed, and most likely, significantly larger than the list presented below. There were too many short, but nevertheless significant collaborative encounters that we likely did not deposit into our long-term memory or written documentation. We apologize for such oversights.

In this spirit, we appreciate the advice given in the three planning meetings in Stanford, Uppsala, and Dölln/Berlin by the following scholars: Peter Behrens, Burton Clark, Gordon Clark, Lorraine Daston, Meinolf Dierkes, Jean-Emile Gombert, Torsten Husén, Gérard Jorland, Ali Kazancigil, Wolfgang Klein, Gardner Lindzey, Renate

Mayntz, Andrew Pettigrew, Denis Phillips, Marc Richelle, Ursula M. Staudinger, Piotr Sztompka, Eskil Wadensjö, Björn Wittrock, and Robert Zajonc.

We would like to extend special thanks to Laura Stoker, who pinch-hit for Nelson Polsby (section editor for Political Science) who was unable to attend the meeting of section editors in April 1998; and to Linda Woodhead, Senior Lecturer in Religious Studies, Lancaster University, who assisted David Martin with editorial work at all phases for the section on Religious Studies.

We also acknowledge the help of scholars who advised Smelser and Baltes at the stage of pulling together the entry lists, proposing authors, and occasionally reviewing the content and quality of articles submitted.

Smelser thanks: Jeffrey Banks, Peter Bickel, Edgar Borgatta, Charles Camic, Jennifer Chatman, Jean Cohen, Michael Dear, Pierre Ducrey, Eckart Ehlers, Sylvie Faucheux, Steven Guteman, Frank Furstenberg, Helga Haftendorn, Peter Katzenstein, David Laibson, Stephan Lauritzen, Douglas McAdam, Eleanor Maccoby, Phyllis Mack, Cora Marrett, Douglas Massey, Donald Melnick, Harvey Molotch, Lincoln Moses, James Peacock, Trond Petersen, Andrew Pettigrew, Alejandro Portes, Matilda Riley, István Rév, John Roberts, Dorothy Ross, Rob Sampson, Fritz Scharpf, Melvin Seeman, James Short, Fritz Stern, Carol Swain, Ann Swidler, Ken'ichi Tominaga, Charles Tilly, Wolfgang van den Daele, Sidney Verba, Margaret Weir, Thomas Weisner, and Jennifer Wolch.

Baltes is very grateful to: Nancy Andreasen, Gerhard Arminger, André-Jean Arnaud, Jens Asendorpf, Jan Assmann, Margret Baltes (deceased), Jürgen Baumert, Peter Behrens, Manfred Bierwisch, Niels Birbaumer, Peter Bloßfeld, Walter Borman, Robert F. Boruch, Mark Bouton, Michael Bratmann, David Buss, Shelley Chaiken, Lorraine Daston, Juan Delius, Marvin Dunnette, Georg Elwert, Helmut Fend, Hans Fischer, Peter Frensch, Alexandra M. Freund, Dieter Frey, Jochen Frowein, Gerd Gigerenzer, Snait Gissis, Peter Gollwitzer, Ian G. Gotlib, David Gyori, Heinz Häfner, Helga Haftendorn, Giyoo Hatano, Adrienne Héritier, Theo Herrmann, Otfried Höffe, Ludger Honnefelder, Paul Hoyningen-Huene, James Huang, Günther Kaiser, Heidi Keller, Martina Kessel, Gábor Klaniczay, Wolf-Hagen Krauth, Achim Leschinsky, Karen Li, Shu-Chen Li, Ulman Lindenberger, Elizabeth Loftus, Gerd Lüer, Ingrid Lunt, Hans J. Markowitsch, Laura Martignon, Randolf Menzel, Dietmar Mieth, Susan Mineka, Setsuo Miyazawa, John R. Nesselroade, Claus Offe, Vimla Patel, Meinrad Perrez, Rosa Lynn Pinkus, Robert Plomin, Neville Postlethwaite, Thomas Rentsch, István Rév, Peter Roeder, Richard Rorty, Hubert Rottleuthner, Peter Schäfer, Heinz Schuler, Norbert Schwarz, Richard J. Shavelson, Joan E. Sieber, Burton Singer, Wolf Singer, Edward Smith, Hans Spada, Günter Spur, Rolf Steyer, Michael Stolleis, José Juan Toharia, LeRoy B. Walters, Elke U. Weber, Peter Weingart, and Reiner Wimmer.

There was one more group that played a special role in the editorial review (see also Introduction). Baltes was assisted by a team of colleagues who provided expert input to the section editors and to him during final review: Gregor Bachmann, Alexandra M. Freund, Judith Glück, Wolfgang Klein, Olaf Köller, Shu-Chen Li, Ulman Lindenberger, Ursula M. Staudinger, and Christine Windbichler. Their expertise in helping us to ensure quality is gratefully acknowledged.

The day-to-day organizational work of the editors in chief occurred at their respective research centers — the Center for Advanced Study in the Behavioral Sciences and the Max Planck Institute for Human Development in Berlin. Smelser singles out Julie Schumacher, his main assistant in the project, for her organization of the meeting of section editors, and her superb coordination of the flow of correspondence and manuscripts over several years. She remained firm when the rest of us were faltering, and displayed the greatest efficiency, intelligence, and good cheer. Smelser also relied on periodic help from Leslie Lindzey, Kathleen Much, Jane Kolmodin, and Anne Carpinetti. Michelle Williams of the University of California, Berkeley, served as his main editorial assistant for nearly 2 years, going over all entry manuscripts from the standpoint of readability, and carrying a great part of the cross-referencing work; her judgment was always the best, and Smelser is forever indebted to her.

At the Max Planck Institute for Human Development, and aside from Julia Delius (see below), Baltes expresses his deeply felt thanks to the main secretarial staff in his office (Helga Kaiser, Romy Schlüter, Conor Toomey) who during the preparation of this Encyclopedia took on larger shares of responsibilities for other projects and occasionally helped out when the editorial office was overloaded. More directly involved in the day-to-day operation of the Encyclopedia was Penny Motley, who efficiently functioned as project secretary during the planning phase. During the main phases of the project, it was Yvonne Bennett who was responsible for secretarial and organizational matters. She deserves much applause for her superb and efficient help in the day-to-day running of the editorial office, making sure that all manuscripts and proofs were processed quickly, and also for assisting with the organization of various meetings. Not least, Baltes thanks the administrative office of the Max Planck Institute, and there especially Nina Körner and Karin Marschlich, for their competent work in managing the project budget, as well as Sabine Norfolk who handled most of the numerous fax

transmissions with ever present smiles and friendliness. Finally, in the Berlin editorial office, thanks are also due to Susannah Goss for her excellent work in translating individual articles into English.

Individual section editors wish to thank the following scholars who gave them substantive advice in their work: Richard Abel, Itty Abraham, John Ambler, Karen Anderson, Mitchell Ash, Alan Baddeley, Boris Baltes, Manfred Bierwisch, Michael Bittman, Sophie Bowlby, John Carson, Shelly Chaiken, Roger Chartier, François Chazel, Stewart Clegg, Carol Colby, Philip Converse, James Curran, Jerry Davis, Natalie Z. Davis, Peter Dear, Juan Delius, Michael Dennis, Josh DeWind, Sherry Diamond, Elsa Dixler, Georg Elwert, Howard Erlanger, Drew Faust, Malcolm Feeley, Nancy Folbre, Michael Frese, Angela Friederici, Lawrence Friedman, Bryant Garth; Victor Ginsburgh; Marcial Godoy, Frances Goldscheider, Calvin Goldscheider, John H. Goldthorpe, Reginald Golledge, William Graziano, Stephen Gudeman, Mauro Guillen, Doug Guthrie, John Hagan, Eric Hershberg, Steve Heydemann, Stephen Hilgartner, Judith Howard, William Howell, Jill Jaeger, Bob Kagan, Joe Karaganis, Roger E. Kasperson, Ronald Kassimir, Robert W. Kates, Wolfgang Klein, Hans-Dieter Klingemann, Bert Kritzer, Kay Levine, Steven Lukes, Michael Lynch, Akin Mabogunje, Stuart Macaulay, Donald MacKenzie, David Magnusson, Michael McCann, Sally Merry, Peter Meusburger, Sieglinde Modell, John Monahan, Kevin Moore, Gerda Neyer, Hiroyuki Ninomiya, Jodi O'Brien, Eva Oesterberg, Mark Osiel, James L. Peacock, Susan Phillips, Trevor Pinch, Wolfgang Prinz, Sheri Ranis, Harry Reis, Estevao C. de Rezende Martins, Marc Richelle, Leila Rupp, Gigi Santow, Austin Sarat, Simon Schaffer, Linda Scott, Tim Shallice, Seteney Shami, Ronen Shamir, Susan Silbey, Wolf Singer, Sheila Slaughter, Gerhard Strube, Ursula M. Staudinger, J. Stengers, Stephen M. Stigler, Michael Stolleis, Mark Suchman, Denis Szabo, Verta Taylor, Ashley Timmer, David Trubek, Leslie Ungerleider, Don Van Arsdol, Jakob Vogel, Rita Vörg, Judy Wajcman, Mary Wegner, Wlodzimierz Wesolowski, Steve Wheatley, Björn Wittrock, and Vincent Wright (deceased).

Section editors also thanked the following persons for their research assistance: Pamela Anderson, Susan Augir, Anja Berkes, Chantale Bousquet, Aida Bilalbegović, John Clark, Susanne Dengler, Kathrine Derbyshire, Annie Devinant, Casey B.K. Dominguez, Barbara Dorney, Elizabeth Dowling, Tracey L. Dowdeswell, Carolyn Dymond, Debbie Fitch, Susannah Goss, Verhan Henderson, Andrew Hostetler, Gudrun Klein, Heike Kubisch, Angie Lam, Ellen Lee, Valerie Lenhart, Kay Levine, Allison Lynn, Helena Maravilla, Carol B. Marley, Marion Maruschak, Michael McClelland, Rhonda Moats, Birgit Möller, Katja Neumann, Linda Peterson, Justin Powell, Paul Price, Xandra Rarden, Chris Reiter, Deborah Sadowski, Heidi Schulze, Heidi Sestrich, Keith Smith, Judith Thompson, Karen Varilla, Stuart Vizard, Danelle Winship.

It is difficult to single out one person as especially helpful. Despite the risks involved, we would like to highlight one person (see also Introduction). As shown in the front matter, beginning in the second year of the planning phase, Julia Delius served as our scientific editorial assistant. For our internal process of editorial review and management, Julia Delius was the mastermind of editorial coordination. Her work was simply outstanding.

Finally, we express our thanks to several individuals at Elsevier publishers whose work was both essential and helpful to us throughout. Barbara Barrett started the ball rolling for the entire Encyclopedia project, and was a master at negotiating out the fundamental arrangements at the beginning. Geraldine Billingham, as executive editor, also played an important role in the development of the project, as well as carrying the heavy responsibility for ensuring that all the financial and operational aspects of the project were realized. She executed this work with directness, skill, and tact. Angela Greenwell coordinated the editorial process with dexterity, calmness, and good judgment. Three persons were responsible for monitoring the progress of entries from Elsevier's side: Michael Lax for a time at the beginning; Jayne Harrison, who carried an overwhelming load of manuscripts month after month, and Helen Collins, who was responsible for the equally demanding job of shepherding the manuscripts through the entire production process. Ruth Glynn skillfully and imaginatively masterminded the development of the electronic version within Science Direct. We know how much the success of the Encyclopedia has depended on these individuals and their staffs, and our appreciation and admiration is here recorded.

Our expressions of gratitude and respect for the authors, section editors, reviewers, counselors, and editorial team, however, are not meant to distract from our own responsibilities as editors in chief. Let us hasten to add, therefore, that those whom we acknowledge deserve most of the credit but little of the blame for whatever shortcomings remain.

Neil J. Smelser
Paul B. Baltes

INTRODUCTION

Alan Sica's article in this encyclopedia observes, "The urge to systematize and rationalize both common and esoteric knowledge has been strongly and continuously in evidence for at least 2400 years in the West" (Sica, 2015). Sica dates the origins of this urge to Plato's nephew Speusippus, who took up the challenge of Plato's call for an *encyclopedia* (from Greek words meaning 'general education'), and traces the urge though Pliny the Elder, Vincent of Beauvois, Francis Bacon, Denis Diderot, and a great many others. Today, an encyclopedia is simply a self-contained reference work "with two aims: to include up-to-date knowledge about a particular discipline or group of disciplines and to make this knowledge conveniently accessible" (Smelser and Baltes, 2001). Such are the aspirations of the present work.

Histories of the concept of an encyclopedia are widely available and need not occupy us here. Those interested in where the *International Encyclopedia of the Social and Behavioral Sciences* (IESBS) fits into the long history of encyclopedias will do well to consult the Sica article quoted above or the Smelser–Baltes 'Introduction' to the first edition of this work.

This is the second edition (2/e) of the IESBS. Elsewhere, I acknowledge my immense debt to the editors of the first edition, Dr Neil Smelser and Dr Paul Baltes. Without their perspective and template to follow in assembling the second edition, this version would have scarcely been possible. The very thought of an encyclopedia covering *all* the social and behavioral sciences, one that drew on scholars from *all* corners of the globe, is itself so audacious that one would hesitate even to begin without a pretty detailed road map to the terrain.

On the occasion of the publication of Robert E.L. Faris's widely acclaimed *Handbook of Modern Sociology*, Joseph Gittler was moved to ask, "With the plethora of new handbooks, reviews, and compendia in sociology, one wonders whether there is a need for yet another one." That question was posed almost 50 years ago; the ensuing half-century has been marked, as Sica says, by "an avalanche of reference materials the likes of which had never been seen in libraries prior to about 2000." So readers and critics are within their rights to ask: Why a second edition? Why now?

The first edition (1/e) was reviewed in *Contemporary Psychology* as "the largest corpus of knowledge about the social and behavioral sciences in existence" (Park, 2004). According to readily available data sources, IESBS 1/e has been cited nearly 6000 times in subsequent scholarly literature and has an h-index ($h = 24$) that would be the envy of many full professors. Citations are only one measure of impact, of course, and probably not the most important measure for a basic reference work intended more for students and a general audience than for practicing professionals. In addition to the thousands of scholarly citations, items from IESBS 1/e were 'hit' almost two *million* times on Science Direct between online publication in November 2002 and August 2014 — two million instances where IESBS 1/e was likely consulted as a basic reference source, to get quickly up to speed in a new area of research or to provide background for a paper or project, or just to satisfy a reader's curiosity. The first edition, in short, emerged soon after publication as a go-to reference work throughout the social and behavioral sciences. Michael Shanahan referred to the first edition as "the atomic bomb of reference works." It was thus an easy conclusion that the work had sufficient value to keep it alive and current.

In reading selected articles from the first edition, however, I was taken aback by how much and how quickly they had aged. The first articles I looked at were those pertinent to my own areas of research and in nearly every case, there was important recent work that I felt needed to be discussed. With the assistance of colleagues in other areas of the social and behavioral sciences, it became obvious that this was a general problem. To be sure, much of the material in 1/e has enduring value; indeed, roughly half the articles in 2/e are updated and revised items from the first edition. Still, it is sobering to realize just how quickly the frontiers of social science

knowledge shift and thus how quickly a basic reference source becomes dated. I am certain there are articles in the current edition that are already in need of some updating.

Smelser and Baltes enumerated six criteria that guided their decisions about what to include and what to leave out. The criteria are as follows:

1. secure knowledge, realizing that security of knowledge is a dynamic and relative term,
2. knowledge with balance and comprehensiveness,
3. knowledge that is integrative rather than fragmented,
4. knowledge that places the evidence into historical and theoretical context,
5. knowledge that highlights connections between topics and fields, and
6. knowledge that combines, where possible, theory and practice.

I would like to say I have followed these same criteria in determining the content of 2/e, but all six criteria have proved problematic in one or another way and thus deserve some comment in light of the present work:

1. What is secure knowledge today is apt to be recognized as wrong tomorrow. Many of our requests for updates to 1/e articles generated some response to the effect, "All of this is completely obsolete. We need to write a new entry from scratch." One would expect this to be true of areas of research such as behavioral genetics, say, or cognitive neuroscience or other fast-moving scientific fields, but it also turns out to be true of archaeology, history, and philosophy. The leading edge of research in *every* discipline threatens received wisdom; those who content themselves with received wisdom ('secure knowledge') will quickly find themselves behind the times. So our charge to authors was to focus less on the 'secure knowledge' in their respective fields and more on the cutting edge — the new perspectives, methods, findings, and issues that will animate social and behavioral science research in the coming decade.
2. Throughout the social sciences, the distinction between theory and ideology is sometimes difficult to discern, and so too the distinction between applied research and community or political activism. We need not invoke Max Weber's conclusions about the impossibility of a truly value-free social science to understand that ideological undertones and political preferences can often be detected in social science research work; sometimes, they are quite explicit. Nor is it much of a surprise to learn that many social scientists struggle, not always successfully, to distinguish between what they want the world to be and what the world in fact is. Such struggles are part of the process by which knowledge develops and are thus in evidence in many of the 2/e articles. It would be unwise to enforce by editorial fiat a consensus on issues that the social sciences themselves have yet to resolve.
3. The fragmentation of knowledge *across* disciplines is far more serious that the fragmentation of knowledge *within* them, although the latter is a problem as well. Many well-informed sociologists, for example, take pride in reading widely and can speak with some authority about what is going on in the field, even in areas of sociology that do not directly concern them. I assume this is also true of the other social and behavioral science disciplines and areas. But rare is the sociologist who is cognizant of work being done, say, in social geography *even when*, as is often the case, the fundamental problems, theoretical issues, and methodological approaches are similar. This is a widespread problem across the disciplines: The evolutionary psychologists do not know as much as they should about what the anthropologists are doing; the economists ignore a lot of pertinent work in sociology and political science; etc. For better or worse, disciplinary differentiation is an inherent element in the process of knowledge development and discovery, so this is a reality to be faced, not a problem to be solved. We dealt with this reality mainly in two ways: (1) Authors were encouraged wherever possible to think across rather than strictly within their disciplines. (2) Calling relevant work done in other disciplines to the reader's attention was a guiding principle for the choice of cross-references for each article.
4. Social-constructionist theories of knowledge would argue that knowledge does not become knowledge until it is placed in historical, cultural, social, political, and theoretical context. As put very simply and succinctly in the opening line of the famous text by Berger and Luckmann, "reality is socially constructed" (1966: 1). This is no less true of social science knowledge than knowledge in any other realm. Unfortunately, a great deal of what we think of as social science knowledge is based on biased samples of WEIRD people — that is, Western, Educated, Industrialized, Rich, and Democratic (Henrich et al., 2010). (The same point has, of course, been made by many others.) The WEIRD, thus defined, represent a rather exotic minority group judged by world standards, and the challenge for IESBS 2/e was therefore twofold: (1) to recruit non-WEIRD editors and authors where possible; and (2) to persuade all authors to incorporate comparative, cross-cultural, and

international themes and perspectives wherever it was possible to do so. This effort was more effective in some sections than in others. Moving away from nation-specific literature, themes, and results to a truly *international* (the I in IESBS) account of the social and behavioral sciences was an ever-present *desideratum* in my discussions with editors and authors.

Alas, an emphasis on cross-culturalism often brings to light that everything, or nearly everything, seems to vary by culture, subgroup, ethnicity or nation, and at that point the question arises whether social science generalization is even possible. Are there universals that cross all social groupings? Or does social science dissolve into a mist of group-specific particularities that adduce no general principles? That hardly seems desirable. Yet myopic and ethnocentric fixations on one's own society or culture are scarcely to be encouraged either.

The worst offenders in this regard tend to be social scientists from the USA (and from the West more generally), who, of course, also comprise the largest share of editors and authors for IESBS 2/e. True, as with greenhouse gases, the USA (and the West) also produce the largest share of the world's science, social and otherwise, and so it is inevitable that they also represent the largest share of IESBS 2/e contributors. The Swedish social anthropologist Ulf Hannerz wrote about this very issue in his marvelous essay, "Editing Anthropology" (Hannerz, 2010). Hannerz quotes a Canadian anthropologist who said of the "neighborly presence" of US anthropology that it was like being "in bed with the elephant." The same is true of most or all of the disciplines covered in this work. But then in a passage remarkable for both its insight and its generosity, Hannerz remarks, "No doubt tensions and conflicts may arise out of this situation, but perhaps it is better to understand that the elephant cannot help being an elephant, and that it makes sense for it, in its habitat, to behave in elephantine ways. A well-trained elephant, too, can do a lot of good, such as in carrying heavy loads." So if the elephant that is Western social and behavioral science has been pressed to carry the heavier load in these pages, that is, the price to be paid for being an elephant in the first place.

The larger issue here is that the social and behavioral sciences, which were largely birthed in the West, in Europe and the United States, mainly address a trans-Atlantic scientific dialogue, a dialogue that is carried out almost exclusively in English. Indeed, throughout much of the world, a scientist's stature is indexed in part by his or her success in publishing in English. Publications in the native language are simply *assumed* to be inferior. The main exceptions, tellingly, are French and German social scientists whose native-language publications are valorized. A Dutch or Portuguese or Hungarian social scientist who only published in the native language would be seriously punished in merit and tenure reviews. Elsevier's citation database Scopus *requires* English-language abstracts before a journal will even be considered for inclusion. And English (with American spellings) is likewise the official language of this encyclopedia. No resources were made available to get articles submitted in other languages translated (although several such articles were submitted). Inevitably, this biases the encyclopedia's coverage in favor of social science addressed to the trans-Atlantic dialogue. Consequently, a great deal of excellent social science published in Spanish, or Mandarin, or Farsi, or any of the other world languages, is overlooked.

That said, steps were taken to improve the internationalism of the encyclopedia's coverage throughout the 4 years of its development. To begin, I sought area and section editors from around the globe and urged them whenever possible to seek international (vs strictly Western) authors. Articles were often returned to their authors with explicit instructions to add international coverage. And when all efforts failed and we ended up with articles that were unmistakably restricted to a single nation in their coverage (frequently but not always, this was the US), I indicated the national focus in the article subtitle. Still, a great deal more WEIRD social and behavioral science remains in these pages than would be desirable in an *international* encyclopedia. In a later section, I give the national breakdown of everyone involved in this project.

5. An encyclopedia that "highlights connections between topics and fields" is easier to envision than to accomplish. Criterion (3) above speaks to the disciplinary fragmentation of our social science knowledge. William Easterly, the NYU economist, has written about the 'tyranny of experts' but the tyranny of the disciplines is an equal problem, a tyranny sanctified by the very academic structure of the modern university, where the separate and often warring colleges are each comprised of assorted departments, the latter representing basic academic disciplines. Interdisciplinary programs are almost invariably relegated to various centers, institutes, or specialized research laboratories — in short, to the periphery of the university's power structure. And while everyone *says* they want to encourage multi- and interdisciplinarity, very little is done to make that happen. Instead, departments remain as the fundamental unit of academic organization.

   Hortatory admonitions to editors and authors have made IESBS 2/e somewhat more interdisciplinary than its several predecessors, but in the end, the disciplinary emphasis in many of our articles would be hard

to overlook. Still, there are many sections of the work that were clearly developed with interdisciplinarity in mind and in which one finds interdisciplinary social science at its current best: environmental and ecological sciences; health; life course; sexuality; GLBT studies; public policy; evolutionary sciences; war, peace, violence, and conflict; and genetics, behavior, history, and society are a few sections that come immediately to mind.

I am particularly pleased with the extensive coverage given in 2/e to the interactions between the biological and social sciences. Harry Whitaker once remarked in a private e-mail that "we are all witnesses to the marriage of biology and the social sciences." Many of the articles found here are offspring of that marriage. And those articles leave little doubt that the future offspring of this marriage will be among the most exciting and insightful social science products of the coming decade.

The social sciences once resisted everything biological as rank reductionism; in addition, the social scientists have always feared that a mature and complete biology would eventually drive us out of business. Articles included in IESBS 2/e make it clear that 'nature' versus 'nurture' was the wrong question from the very beginning, that what we need to understand is how biological inheritance and social and cultural forces *interact* to produce individual and collective outcomes. This is where a lot of the interesting action in the social sciences is going to be in the coming years.

6. The coverage of the practical or applied sides of the various disciplines has been increased in this edition, so the applied content of 2/e certainly exceeds that of its predecessor. New to this edition is the entire section on applied social and behavioral sciences; also new is our large section on social work and the separate section on applied, industrial and organizational psychology. But as Sara Strickhouser and I say in our article on the history of applied social research, "The history of 'applied social science' is indeed the history of the social sciences themselves" (Strickhouser and Wright, 2015). All of the social sciences in their modern form were birthed in the post-Enlightenment effort to understand why people, their institutions and society as a whole were as they were — why greed was more visible than generosity, why oppression was more common than freedom, why inequalities of various sorts characterized every social institution. To the founders of the disciplines, the modern distinction between basic and applied scientific concerns would have seemed meaningless, as indeed it was.

The Planning Phase and Editorial Structure

Elsevier's original acquisitions editor for this project, Scott Bentley, discussed the broad outlines of our attack on IESBS 2/e with me in a series of phone calls in the early months of 2010. By May 2010, certain of these outlines had come into sharp relief. There would be a single editor in chief with a tier of 'responsible lieutenants' to assist. These lieutenants started out as advisory editors but soon morphed into the 10 area editors in the final editorial structure. Each area editor would in turn oversee various sections and each section would have its own editor or editors. The original plan was that the area editors would each be responsible for approximately 400 articles and each section editor responsible for about 100 articles, so that no one would have an excessive amount of work compared to everyone else. In the end, however, some sections required more articles and others fewer, so the areas vary from fewer than 300 to more than 600 articles, and the sections vary from fewer than 30 articles to well more than 200.

Prior to my first discussions with Scott Bentley, Elsevier had commissioned about 20 'market surveys,' roughly half from professional librarians and the other half from academics, each focused on 'what was right and what was wrong' with the first edition. The most insistent demand that surfaced was for a fully electronic, computer-searchable work either in addition to or instead of a print version. In the end, both an e-version and a print version are being made available. But there were also consistent concerns expressed about spotty coverage of some areas: no coverage of social work to speak of; inadequate coverage of accounting, marketing, and business; no separate section of criminology; haphazard coverage of applied topics and concerns; and so on. And there were the predictable concerns about undue Western domination of the work.

Working from the 1/e Table of Contents and this stack of 20 surveys, I tinkered for a few months with how best to expand coverage to address the concerns our reviewers had expressed; the result was (more or less) the editorial structure shown elsewhere in the front matter of this work. Thus, the 53 sections of 2/e are basically the 39 sections of the first edition plus sections that were added to cover important emerging areas of research interest (e.g., gay, lesbian, bisexual, and transsexual studies) or to provide deeper coverage of disciplines and subdisciplines that the first edition treated lightly if at all (applied social and behavioral sciences, social work). A

few of the first edition sections were eliminated entirely: specifically, integrative concepts and issues (something of a catch-all category for 1/e articles that were highly interdisciplinary or simply did not fit anywhere else) and gender studies (gender is now so thoroughly integrated into the research and thinking of all the social and behavioral science disciplines and subdisciplines that a separate section was unnecessary and somewhat retrograde). Others were altered or expanded in significant ways (organizational and management studies, for example, became the second edition section on management, organizations, business, marketing and finance; expressive forms evolved into the 2/e section on culture and the arts; linguistics was subdivided into three separate sections; etc.) And some subdisciplinary areas that were part of other sections in the first edition were given their own sections in the second (life course studies; sexuality; criminology; labor studies; and war, peace, violence, and conflict are the most prominent examples), just to ensure adequate coverage.

The Introduction to 1/e (Smelser and Baltes, 2001) discusses at great length the intellectual architecture of the first edition and its evolution; the agonizing decisions about rules for the biographical articles; whether to organize the work by discipline, by concept, by an a priori taxonomy of social science knowledge, or in some other manner; and related structural matters. What resulted in 1/e was something of a hybrid model with some sections clearly representing specific disciplines, others representing 'overarching topics,' still others representing 'intersecting fields,' and so on. My task was far less challenging: I thought the architecture of the first edition served its purposes admirably and so I adopted it wholesale for the second edition, with the small modifications noted above.

While each of the 53 sections of 2/e has some more or less obvious justifying logic or substantive or disciplinary coherence, their arrangement into the 10 areas of the second edition does not. As already indicated, decisions about what sections to include and exclude were made very early in the development of the second edition, based on what was in the first edition, what Elsevier's marketing surveys suggested as significant lacunae, and my own sense of things. The arrangement of the sections into areas came later and was dictated largely by the interests and expertise of those who had been persuaded to sign onto the enterprise. Thus, all the Linguistics sections are in Area Five along with the cognitive and neuroscience sections because Harry Whitaker at Northern Michigan University had been a linguist first, a neuroscientist second, and a historian of psychology third. Likewise, Area Eight contains its seemingly chaotic hodgepodge of evolutionary sciences, genetics, religious studies, science and technology studies, and law because these happen to be the fields of interest of the redoubtable Barbara Prainsack of King's College, London, whose editorial talents are as deep as her interests are broad. Simplifying only slightly, section editors were chosen for their substantive expertise in particular areas of research (as well as their international or cultural 'range'); the plan was that section editors would review each of their articles for completeness of coverage, currency, fairness, and the like. In contrast, area editors were chosen for their breadth of interest and knowledge spanning multiple sections – people who by nature, experience, and training would be good at seeing the big picture. The role of the area editors was to assure that the articles were at least modestly international and interdisciplinary and formed some sort of coherent whole.

As laid out in an early e-mail to one of the area editors, "In my mind, Advisory [Area] Editors are generalists and Section Editors are content specialists. The Section Editors need to bring breadth of knowledge to their responsibilities, of course, but the primary job requirement is expert understanding of the particular field or section. We need section editors who can commission pieces that adequately review past developments in the subject area, but who can also shape their portfolios to identify major unanswered questions and new research developments." This was the general model followed throughout the recruitment process.

The approach just sketched inevitably left a residual area made of up sections that none of the other area editors were willing or able to claim. That proved to be Area Ten. A very large number of scholars from various disciplines and world regions were approached about serving as the Area Ten Editor. All demurred until I approached Martin Bulmer of the University of Surrey, who served the project for about a year but was unable to continue and subsequently left the Board. So for the final year of the project, the editing of Area Ten was done mainly by me.

The online subject classification for IESBS 1/e did not correspond precisely to the sections of the first edition; the subject classifications listed articles by broad general topic regardless of which 1/e section developed them. So for the first year or so, my assistants and I labored to assign every 1/e topic to one of the 53 2/e sections. With 53 sections to populate with articles and about 4000 articles to classify, the process of assigning articles to unique sections occupied huge amounts of time and generated endlessly complicated spreadsheets. (After about a year of this, a document surfaced in the Elsevier archives that showed exactly where each 1/e article had originated.)

Along with populating the 2/e sections with articles, searching for area and section editors occupied a major part of the early going. The original idea was to identify the 10 area editors first and then enlist them in the

search for their section editors, but in fact, these processes were simultaneous and were about half-completed when the two planning meetings were held: the first in San Diego on 19 and 20 May 2011; the second in London on 5–7 June 2011. Although not part of the plan, the first meeting was mostly attended by area editors and the second, by section editors.

The agenda for both meetings was largely identical: achieve clarity on the respective roles of the various editors; solicit advice on filling the unfilled editorial slots; get buy-in on the project *mantra* (internationalism, interdisciplinarity, inclusiveness!); explain the relationship between the first and second editions (e.g., that all 1/e authors would be offered the opportunity to update their articles); explain the process of assigning articles to sections; and the like. In almost all cases, consensus was quickly forthcoming.

The largest substantive change in the second edition is the treatment of psychology. (Whether measured by students, practitioners, professors or programs, psychology is the largest of the social and behavioral sciences.) In the first edition, the whole of psychology was contained within four large sections: clinical and applied psychology; developmental, social, personality, and motivational psychology; cognitive psychology and cognitive science; and behavioral and cognitive neuroscience. Cognitive science and neuroscience are, of course, rapidly growing sectors of the psychological discipline and it seemed appropriate to devote an entire area of the second edition to them. This area contained seven separate sections (three of them devoted to linguistics). And the 'softer' psychological sciences were placed in a separate area comprised of eight sections (including psychiatry and social work). These changes were made to assure that 2/e had adequate coverage of the entire psychological enterprise (a concern that was raised in some of the reviews of 1/e).

The structure of the editorial team was developed to serve two purposes: first, to divide up the labor into manageable parts; and secondly, to assure that every article in the final product would be reviewed by at least three scholars: the respective section editor, area editor, and the editor in chief. Since we were all aware of one another's identities throughout, the review process was not blinded, but every article in this work has been thoroughly peer-reviewed and vetted. In many cases, these articles have been through four, five, six, or even more revisions before being accepted for inclusion in the work.

Recruiting Editors and Authors

IESBS 2/e faced two different recruiting tasks: recruiting editors and recruiting authors. As indicated elsewhere, the original plan was that I would recruit area editors largely from my own personal networks and they in turn would recruit their section editors. In practice, the process was much more convoluted. First off, many of my 'first choice' candidates were hesitant to involve themselves in such a daunting and ambitious project. In some cases, an initial agreement to come aboard was followed a few weeks or months later by withdrawal as the true scope of work came into sharper focus. Some people that I tried to recruit as area editors demurred but agreed to serve as section editors; in other cases, candidates for area editors were nominated by section editors. In a couple of cases, there was a complete team of section editors prior to the successful recruitment of a corresponding area editor. And so on. The process of assembling an editorial team for the project was by no means linear.

Personal networks – mine and those of the people I persuaded to sign on – were the largest single source of ideas for other editors, by far. But personal networks tend to follow disciplinary and national lines and become rather quickly exhausted. In selecting both editors and authors, it was of course essential that all relevant perspectives be covered and that the breadth of fields was adequately represented. So other sources of ideas were tapped: the expertise of the Major Reference Works team at Elsevier; editorial boards of leading journals in the respective fields; Google Scholar citation counts; the knowledge and networks of people who had been involved in preparing the first edition – basically, anywhere names of top scholars in particular areas could be located. I did not keep systematic track of the number of people approached, much less of the outcomes; but in reviewing my e-mail archives from the early period of the project, I probably asked (on average) somewhere between six and eight prospects before I found someone to agree (an average that was highly variable across the areas and sections).

In the initial plan, area editors would recruit their own section editors and the section editors would in turn recruit their own authors, but the reality was again different. Inevitably, my negotiations with prospective editors (both types) would often result in a declination of the editorial role but an offer to write an article on a particular topic (or topics), offers I readily accepted. So in some cases, I had committed authors of particular articles well before I had the corresponding section or area editor in place. And many of the section editors likewise leaned on their area editors and on me for author suggestions, contacts, and outreach. So all the editors

were involved in locating willing authors (and not coincidentally, in making suggestions for articles to be included in the final work).

No one was asked to keep precise statistics on how many authors were sought before an agreeable author was found. My sense is that the 2/e editors had a somewhat tougher time with this than the 1/e editors had (but on the other hand, the 2/e editors had all the 1/e authors to work with, which Smelser and Baltes certainly did not have). The 1/e editors report that about 60% of those invited to write articles agreed to do so on the first 'ask' (with equivalent success rates in each subsequent 'ask'). In 2/e (or so I would guess), the success rate was probably closer to 50% and possibly even lower. They also report that something in excess of 90% of those who agreed to write for 1/e in fact contributed "acceptable entries in time to be included…" In the 2/e case, we found ourselves still soliciting authors within a few weeks of the submission deadline and some dozens of authors pulled out of the project at the last minute. Still, when all the dust settled, there were just about 800 articles planned for both editions that never materialized and both editions ended up with just fewer than 4000 articles. Perhaps these are 'natural limits' for a work of this sort.

Biographies*

In the Introduction to 1/e, Smelser and Baltes provided a short history of and rationale for the decision to include a limited number of biographical articles (150 of them, to be exact). This was evidently a controversial and contested decision since some of those associated with 1/e felt that biographical articles had no place in an encyclopedia focused on substantive knowledge (versus the personalities of those who produced it). As Newton said (paraphrasing a passage from Bernard of Chartres), "If I have seen further, it is by standing on the shoulders of giants" (a passage made famous among social scientists by Robert K. Merton's *On the Shoulders of Giants* (1965)). In other words, discovery is only possible because its discoverer is able to refer to knowledge already gathered and accumulated by his or her predecessors; and since all discoveries – small and large, substantial and minor – contribute to the production and accumulation of knowledge, singling out particular scholars for special attention would be both pointless and invidious.

This position, although understandable, was abandoned in the first edition and remains so in the second, largely because it is not possible to understand the social sciences without knowing the individuals who contributed to it. C. Wright Mills once defined the sociological imagination as the intersection of biography and history (Mills, 1959). To know the social sciences therefore requires biographical and historical knowledge. The social sciences are distinguished from the physical and biological sciences in the way they produce knowledge because individual human beings, including social scientists, invest meaning in their actions. Only through understanding the meaning that individuals give to their actions are social scientists able to provide explanations of human behavior and its outcomes. And what applies to social action in general applies to the production of social science knowledge as well. It thus makes sense to include biographical accounts of social science personages who have been particularly distinguished in making sense of human action and have in turn made major contributions to social science knowledge. To acknowledge individual social scientists with biographical articles is also to acknowledge their special and particular insights.

Once the decision was made to include biographies in 1/e, the next major decision was whom to include and whom to leave out. Two arbitrary but defensible principles governed these decisions: (1) the total number of biographies was not to exceed 150 (chosen because it seemed like a manageable number) and (2) only biographies of the dead would be included. The 1/e section editor for biographies, Karl Ulrich Mayer, consulted handbooks and encyclopedias, asked other section editors to name and rank the most important names in their respective disciplines, ran citation checks, and finally submitted a consolidated list to various experts for review. This resulted in some additions and some deletions and in the end 147 biographies made it into the first edition.

Instructions to authors writing these biographies directed them to include "a brief sketch of the major dates and events in the life of the biographee," to describe "the major contours of the [person's] substantive contribution," and to highlight the "importance and relevance of the biographee's work for the social and behavioral sciences." Largely the same instructions were given to 2/e biographers.

The selection criteria for 2/e were very different. First, on the reasoning that well-done biographies of leading figures is one of the things that draw readers to a work such as this, the total number of biographies was

* My thanks to Andreas Hess for drafting this section of the Introduction.

increased by more than 100 (to just over 250). In a major departure from 1/e, much of the increase is made up of biographies of the living. The 1/e restriction that excluded living persons resulted in anomalies that we thought needed to be addressed. As life expectancy has expanded in the twentieth and twenty-first centuries, so have the life spans of social scientists. Claude Levi-Strauss, to cite one obvious example, lived to the age of 101 years. When 1/e was published, he was in his 90s, was widely cited, was recognized universally as a modern classic, indeed a genius, of social anthropology – and yet, owing simply to his longevity, he was not included in the 1/e biographies. Biographies of, for example, the economist Herbert Simon, the political economist Albert O. Hirschman, the sociologist and philosopher Jürgen Habermas, and the linguist Noam Chomsky were all excluded for the same reason; indeed, Habermas and Chomsky still live as this is being written (Fall, 2014). In all these cases, the major works had been produced decades earlier, their major imprints on the social and behavioral sciences were already evident, their eventual inclusion in works such as this was inevitable. Are readers to be deprived of accounts of their lives, times, and contributions just because they have survived into deep old age?

Once the decision was made to include biographies of the living, however, it was not always easy to decide who among the living merited inclusion. Often the editors had to make decisions on a case-by-case basis, frequently in extended consultation with colleagues or experts in the field. Criteria used to make these decisions were whether the potential biographee had a reputation beyond one culture, nation, or language group; whether there was a record of sustained production over several decades; and whether there was an impact beyond the confines of a single discipline. These criteria reduced our list of suggested biographees considerably. Early lists of candidates numbered as many as 200 new names (in addition to the 147 biographies included in 1/e). In the end, as noted earlier, somewhat more than 100 new names were added.

In a few cases, persons were included that arguably did not satisfy our inclusion criteria. One such is Raul Hilberg, who became famous mainly for having written one very important book, *The Destruction of the European Jews* (1961). Hilberg's book is still regarded as the seminal work in Holocaust studies, a field of research that came to prominence much later; we felt that his signal contributions to Holocaust studies merited a biographical article. Much the same could be said, perhaps, of André Gorz, a well-known social theorist from France, and Albert Memmi, whose work is on colonialism, anticolonialism, and racism. These and other examples could and probably will raise questions about the porousness of our criteria. Whether we were right in giving 'trespassers' their space is open to debate. In any case, whether Hilberg, Gorz, Memmi, and others do or do not merit their biographies is for readers, not us, to decide.

Other important changes in the 2/e biographies section include, first, a conscious effort to attain a better gender balance, including more women both as biographees and as authors; and second, expanding the biographies both geographically and culturally. In the end we made some inroads in both respects but fell short of our internal goals. One of the main reasons for this is that any encyclopedia must, in the first instance, be true to the disciplines it represents. This means being true to the real status of important players, their networks and disciplinary power relations, and their academic capital in their respective fields and beyond. Change in these respects has been noticeable; certainly, the growth of the social sciences in Asia has been remarkable; and in most disciplines, the proportional presence of women has increased. But modest change in the right direction does not a revolution make. Too many nonwhite, non-Western, and nonmale practitioners are still being left out on the disciplinary peripheries and are not fully represented – not in their home disciplines and not in our encyclopedia either.

We state this fact with regret. In many cases, the limiting factor is not excellence but simple visibility. Being part of the trans-Atlantic social science dialogue and engaging this dialog mainly in English translates into more visibility, as discussed earlier. This gets a scholar on the radar screen. Equally excellent work engaging other intellectual dialogues in languages other than English does not. A great many outstanding scholars have thus gone unrecognized in 2/e for precisely this reason. That being said, strenuous efforts were made to make the 2/e biographies more inclusive. Among those included are the Argentinean educationalist Sarmiento, the Brazilian sociologist Cardoso, and the Japanese political scientist Maruyama, to name just a few. This is, however, 'just a few' of the many dozens of prominent social and behavioral scientists 'out there' whom we would have included had we been given more time and more resources (to get non-English works translated, for example). We do feel that we have made some important inroads and beg the reader's understanding of the limits within which we worked. We can only hope that the next edition will strive for more inclusiveness and better representation than we were able to achieve.

Another entirely new feature in the 2/e biographies is the series of 'collective biographies.' In many instances, the intellectual lives of individuals who work in research groups intersect and form a network that makes the

entire group (or paradigm) successful. Examples include articles on the Durkheimians, the Annales School, the Frankfurt School, and several others.

As indicated earlier, instructions to authors were changed little from 1/e. All authors were asked (1) to include the most important biographical facts (country of origin, generation, education, influences, other formative experiences, networks, etc.); (2) to list the most important output (discoveries, publications, etc.) and to briefly discuss the subject matter and content of the most important publications or discoveries; (3) to look at the lasting impact of the person and his or her work (if possible, beyond just one discipline, language group, or culture); and (4) to provide a bibliography of primary and secondary sources related to the biographee and his or her work. Most authors stuck to these guidelines.

Finally, we state for the record that there are a number of important social and behavioral scientists that we would have liked to include but for whom we were unable to find a proper biographer. The search for biographers went on for nearly 4 years. In many cases, our first-choice author agreed at once, but in other cases, we approached four, five, or even more people before an agreeable author was found. And in about two dozen cases, no such author was ever found, with the result that a deserving person's biography had to be dropped. Forgoing a case-by-case discussion of these deletions, let it be simply noted that this is why we have not included biographies of people such as Amartya Sen, the economist and social philosopher; Raymond Boudon, the French sociologist; Ronald Dworkin, the legal theorist; Avishai Margalit, the philosopher; or a collective article for the British Marxist historians (Eric Hobsbawm, E.P. Thompson, Christopher Hill, and Perry Anderson). Perhaps our most regrettable omission is Neil Smelser himself, for whom no biographer could be found despite at least a dozen attempts. (Paul Baltes's biography is included.) Neil is one of the giants on whose shoulders we all stand.

Redundancy

I mentioned earlier that in the beginning of the project, there was no 'map' linking each of the 1/e articles to its respective 1/e Section. Our efforts to create such a map invariably bogged down every time we hit an article that could plausibly belong to any of several sections, which was often. Obviously, it would have been possible to force every article into a 2/e section, but at the time it seemed advisable to involve the editors themselves in these decisions. So on numerous occasions, I distributed lists of 'orphaned' articles (articles for which no home had yet been designated) to the area and section editors, asking for foster parents to volunteer. Eventually, of course, every article found a home, but at a relatively late date in the process, I became aware that a few dozen articles had found more than one home. That is, some of the editors adopted articles without filing the appropriate paperwork with the editor in chief! In such cases, the result was two articles on the 'same' topic. (The 2/e Table of Contents was scoured multiple times looking for precisely these kinds of duplications but in the end, several proved elusive.)

In the large majority of cases, the content of the 'duplicate' articles was sufficiently distinct that both articles were retained, often with some retitling to help readers differentiate between them. For example, readers will find two articles on 'social identity.' One was recruited for the section on social psychology; the other for the sociology section. With rare exception, the two articles discuss different aspects of social identity from entirely different disciplinary angles; indeed, the two articles share only a small handful of common references. So it was an easy decision to retain them both: one appears here as Social Identity in Social Psychology; the other as Social Identity in Sociology. Careful readers will find perhaps a score of similar cases in the encyclopedia.

Alas, in a few regrettable cases, the overlap between duplicate articles was so pronounced that one of the articles had to be deleted. Since by the time these problems surfaced the articles had (often) been written and rewritten several times and had been accepted by both the section and area editors, the last-minute decision to delete a redundant article was painful. My sincere apologies to the authors involved.

Some redundancy in a work of this scope and aspiration is not only inevitable, it is probably also desirable. A reader interested in, say, social inequality will (one hopes) want to know what the sociologists, anthropologists, economists, and geographers all have to say about that topic. And if a few of the many articles on the topic say more or less the same thing, then what harm is done? Editors at all levels were asked to be alert to redundancies across articles and the editorial record shows that many were. That being said, quite a bit of topical redundancy no doubt remains, and that is not (in general) a matter of concern. It is what Smelser and Baltes refer to as the "inevitable residue of overlapping."

The Review Process

Once the table of contents had stabilized, each of the editors was asked to review the 1/e articles assigned to their section or area and come to various decisions. In some cases, 1/e articles could be reprinted more or less 'as is,' with perhaps some updating of references for readers seeking entry points into the current literature. This was especially the case with what were eventually designated as 'legacy articles,' e.g., Gabriel Almond's article on Civic Culture, James Gregor's article on Dictatorship, &c. In other cases, the 1/e articles needed some updating to be suitable for 2/e, either by their original authors when available or by others recruited specifically for the purpose. The general rule was that all 1/e authors would be offered the opportunity to do the updates themselves, and that other authors would be sought in the event of the original authors' declinations. In still other cases, the 1/e article was so obsolete than an entirely new article would be required. And then finally, the review of 1/e articles often revealed areas of current research that were inadequately covered; in these cases too, completely new articles would be sought.

Where appropriate, the relationship between the 1/e and 2/e versions of an article is spelled out in the article tagline. In many cases, there were issues of authorship to resolve — a 1/e article written by *X* and completely revised by *Y* is *Y*'s article although *X* might be identified in the tagline; but what of an article written by *X*, now deceased, and only modestly revised and updated by *Y*? Every decision rule that I formulated to resolve such issues soon confronted an exceptional case where the rule did not seem to apply. So in the end, the only workable rule was that everyone should get proper credit for their intellectual property, whether prime author or reviser, whether living or dead. If exceptions to this rule have crept into the final product (as they almost certainly have), I offer my apologies to those whose work has been slighted or improperly recognized. Deciding on proper authorship for many of our articles was a far more involved and difficult task than expected.

The section editors formed the first line of editorial defense and were the ones to whom article drafts were originally submitted. The section editors read and commented upon the draft articles and returned them to authors for revision. It is a rare article that appears here in its original form: on average, articles were revised two or three times before being sent to the area editors and subsequently on to me; in many cases, it was more like five or six revisions, with subsequent revisions at the request of the area editors and the editor in chief. And in some cases, articles were submitted to outside readers for independent review. As I stated earlier, the reviewing process was not blind, but it was quite thorough, as is reflected in the exceptional quality of the final product.

Internationalism and Inclusivity

A truly *International* Encyclopedia of the Social and Behavioral Sciences would of course require a global network of editors and authors *and* a commitment to internationalize the content of the work wherever possible. With respect to the editorial team for 2/e, this was definitely realized. The section editors and editors in chief who produced the first edition were drawn from only nine countries: The United States, Germany, Italy, Canada, Sweden, Australia, France, Switzerland, and the UK. Two-thirds of those editors were from the USA and only 13% were women. Area and section editors for 2/e represent 21 countries, US scholars make up only 38% of the total, and women comprise 36%. Thus, the proportional representation of women among the editors was nearly tripled in 2/e over 1/e while the predominance of the USA was halved. Nations represented among the editors of 2/e that were not represented in 1/e include Luxembourg, Greece, Finland, Japan, China, Ireland, Singapore, Spain, Russia, Austria, Israel, and the Netherlands. The presence of several Asian nations on this list is particularly gratifying. To be sure, the North Americans and Western Europeans still predominate, but they no longer monopolize the field.

Adding the International Board of Consulting Editors (see the following statement of Acknowledgments) increases the internationalism of the editorial team even further. Of the 45 members of that Board, only 12 (27%) are US social and behavioral scientists. Countries represented on that Board that are not otherwise part of the editorial team include three Central and South American nations (Venezuela, Argentina, Costa Rica), several Asian nations (the Philippines, Malaysia, South Korea, India), a few Western European nations (Norway, Denmark), two representatives from Central and Eastern Europe (Hungary, Croatia), two from the Middle East (Lebanon, Qatar), and one from South Africa. These editions bring to 35 the total number of countries with representation on the IESBS editorial team.

Much the same can be said of the 2/e authors, who are also more international than the 1/e authors had been. Smelser and Baltes noted in their Introduction that while authors from 51 nations were represented in the work,

58% of the authors were from North America and another 35% were from (mainly Western) Europe. "As to gender composition, 21% of the [1/e] authors were women." In 2/e, the proportion of women among the authors has increased slightly to approximately 25% and the percentage of North American authors has declined to fewer than half. Again, North America and Western Europe still contribute the larger share of the 2/e authors but the growing representation of social and behavioral science authors outside the West is both noteworthy and encouraging.

Another important point is that the international scope of the project is much more pronounced than editors' and authors' current affiliations would lead one to conclude. (This would have been equally true in 1/e as well.) Consider, for example, Michiru Nagatsu, author of our article 03053 on the history of behavioral economics. Dr Nagatsu was born in Japan and retains Japanese citizenship but was educated at Exeter and the London School of Economics and Political Science and wrote his IESBS 2/e article while on a postdoctoral fellowship in Finland. Or Guillermina Jasso, area editor for Area Three. Jasso was born in the USA, received her PhD from Johns Hopkins, and is on the faculty at New York University. By any standard, she would count as a US sociologist in our compilations. Yet her parents were Mexican of Basque, Spanish, Portuguese, and Dutch origins; Spanish is her native language; over the course of her distinguished career, she has published with coauthors from Germany, India, Israel, Mexico, the Netherlands, and Sweden; and she holds a permanent research fellowship at IZA, the Institute for the Study of Labor, in Bonn, Germany. Scoring her as 'USA' scarcely does justice to her biography or to the international perspective she brought to the editorial task.

What is true of author Nagatsu and editor Jasso is true in degrees of virtually the entire roster of IESBS participants. If one includes place of birth, citizenship, where educated, sites of research, visiting appointments, sites of fellowships, honorary professorships, invited lectures, and on through the list of highlights in a modern academic career, it is safe to say that every nook and cranny of the globe (save, possibly, Antarctica) is represented somewhere in the biographies of IESBS authors and editors. The true measure of internationalism, in short, is not so much where people come from or where they currently are, but rather the extent to which they bring a sensitivity and commitment to cultural and national differences into their work. Whether this was or was not realized in 2/e is for readers to decide.

Concluding Observations

Smelser and Baltes aspired in the first edition of this work to "assemble the whole range of knowledge – vast and complex as it is – of the social and behavioral sciences in one place." Since what does and does not qualify as 'social and behavioral science' is itself contested, it is not surprising that nearly every one of the market reviews commissioned by Elsevier to guide the development of the current edition noted content omissions in 1/e that reduced its usefulness and that needed to be addressed in a second edition. Critics can and no doubt will say the same about 2/e. I have already mentioned the nearly 800 articles that appeared on the 2/e Table of Contents at one time or another but that will not be found in the final product, either because agreeable authors could not be located or (less often) because agreeable authors never produced an acceptable article. And it is pretty easy to identify whole chunks of present-day social and behavioral science that are given short shrift, or no shrift at all, in this work – not because these chunks were judged to be unimportant but because limits of time, space, resources, and networks meant that some elements of the contemporary social science enterprise never came to our attention.

The social and behavioral sciences begin with what artificial intelligence guru Marvin Minsky once described as a "three pound computer made out of meat" – the human brain, which for all we know is the most complicated three-pound hunk of matter in the universe – and end with a thoroughly globalized culture and social structure that encompasses all aspects of our species' physical, biological, psychological, social, emotional, cultural, and spiritual lives. We are the most successful species ever to have inhabited the planet; we have colonized every inhabitable piece of dirt; our range extends everywhere; all the earth's resources lay at our command. To record all that has come to be known about human origins, evolution, language, culture, and social structure – everything we know about human emotions, identity, love, religion, family, economics, politics, domination, exploitation, and on through a very long list – would require orders of magnitude more volumes than the mere 26 volumes that comprise the present work.

We have come increasingly to the realization that what is social and human about our species is very intimately connected to our biological, genetic, and evolutionary inheritance. At the same time, the brain specifically and biological evolution more generally "cannot be viewed separately from the material, historical and

social circumstances that produce it" (Berntsen and Baker, 2015). As these authors put it, biology and culture are 'mutually constitutive.' Fifteen years ago, the editors of the first edition remarked on "ferment at the boundaries between the biological and the behavioral and social sciences." And while there are still important controversies, much of the ferment has yielded to cooperation as we are just now beginning to explore this endlessly complex web of interconnectedness between our biological and social selves. It is an easy and nearly inevitable conclusion, thus, that the third edition of the IESBS will contain a great deal more of the work being done at this intersection than 2/e was able to accommodate.

To conclude on a purely personal note, the 5 years I have spent working on this project produced many professional and personal gratifications, none quite so delicious as the certain knowledge that I would learn something new every single day. My work on 2/e exposed me to literature I never knew existed and to aspects of the social and behavioral sciences of which I was at best dimly aware. I can only hope that readers who come to these pages will find them as enriching as I have.

ACKNOWLEDGMENTS

A work of this scale is inevitably a communal enterprise involving many hundreds of editors, authors, reviewers, technical support people, colleagues, professional acquaintances, and friends who have provided input, advice, encouragement, and assistance over the past five years. Any listing is bound to be incomplete, so my apologies in advance to those who expected to be mentioned here but are not. Be assured that the slight is not intentional.

My negotiations with Elsevier about this project began early in 2010. By May of that year, I had committed to the project and have been working on it at varying levels of intensity ever since — often on weekends, during holidays, and whenever else I could snatch a useable chunk of time. So my first acknowledgment must be to my wife Chris for suffering through my five year obsession, always with understanding and affection, usually with good cheer. Chris is probably the only person in the world who is happier than I am that the project is now completed.

I must also acknowledge an enormous intellectual debt to the editors in chief of the first edition of the *International Encyclopedia of the Social and Behavioral Sciences*, Drs Neil Smelser and Paul Baltes (the latter now deceased). Dr Smelser was gracious enough to serve as Chair Emeritus of the project's International Board of Consulting Editors and to put himself at my disposal as, in his words, "a battle-scarred veteran." The basic intellectual structure of this work is adopted more or less wholesale from the Smelser—Baltes edition, with a few exceptions noted earlier in the *Introduction*. Without the original to serve as the starting point and blueprint, it is hard to imagine even embarking on such a task, much less bringing it to completion. Their edition was hailed as "the largest corpus of knowledge about the social and behavioral sciences in existence," which is to say that it formed an *extremely* solid foundation from which to build the work you now hold in your hands.

The first edition was organized into 39 sections overseen by a team of 53 section editors. The structure of the second edition is slightly different. It is divided up into 10 broad 'Areas,' each with an Area Editor overseeing the work of between four and eight Section Editors. In all, the second edition is thus comprised of the 10 Areas subdivided into 53 Sections; the 53 Sections were developed by a team of 76 Section Editors. So whereas Smelser and Baltes had 53 colleagues to help complete the work, I had 84 (two of the Area Editors also edited their own sections). On pages i-v in the front matter to this work one finds an Editorial Board list showing the Area Editors, Section Editors, Sections, names, and affiliations of the entire editorial team — a team whose dedication and effort in behalf of the project has vastly exceeded the rate of pay. A more helpful, productive, or delightful group of scholarly collaborators is difficult to imagine.

What readers see in the listed Editorial Structure of the work is the *final* editorial team as it existed when the work went into production. As would be expected in a project of this duration, there was considerable turnover within the team as the project developed and as death, competing demands, and general indifference all took their toll. I am grateful, nonetheless, to everyone who agreed, at least initially, to participate in the project, whether or not they were able to stay involved to the very end.

Susan Hanson (Geography) and Ulf Hannerz (Anthropology) are owed a special note of thanks because, of the 53 Section Editors involved in the first edition, these are the only two who agreed to reprise their roles in the second. (Both also wisely requested and received coeditors to carry part of the load.) Persuading people to serve who had no real idea what they were getting into was challenge enough, but these two suffered through 1/e and were willing to do it all over again for 2/e. And for that, I am especially grateful.

Many of the editors benefitted from the assistance of colleagues and graduate students at their various institutions. There was no mechanism built into the editorial process to keep systematic track of this

assistance and so the listing below is certain to be incomplete. But I can at least acknowledge those of whom I am aware who contributed time and intellectual energy to the effort: Liam Morton and Andrea Livingstone (Psychiatry); Jennifer O'Connor and Alana Dorris (Applied, Industrial and Organizational Psychology); Jen Hanis-Martin (Sexuality); David Budde, Annette Stimmer, Nikolas Ott, and Franziska Pfeifer (Institutions and Infrastructure of Social and Behavioral Sciences); Matthew LeDuc and Scott Freeman (Contemporary Cultural Concerns); and Simone Dudziak (Public Policy). To those named, my thanks. To those omitted, my apologies.

A special note of thanks to Dr Donald J. Barrett. Don was originally recruited to develop an entirely new section of the second edition on Gay, Lesbian, Bisexual, and Transsexual Studies, completed the section in short order, then e-mailed me to ask if there was anything further he could do to be helpful. Consequently, he took a major hand in developing the section on Biographies and was quite helpful with many other sections too. He appears in the Editorial Structure both as a Section Editor and as a Senior Editorial Associate to acknowledge his yeoman service to the entire enterprise. Also listed as a Senior Editorial Associate is my colleague Dr Amy M. Donley, who has been with the project since the very beginning and who, more than once, was all that stood between me and madness. I am proud to count them both as colleagues, collaborators, and friends.

I am also pleased to acknowledge Don Barrett, Andreas Hess, Harry Whitaker, John Berry, Barbara Miller, Scott Bentley, and Claire Byrne for their incisive and helpful commentary on previous drafts of the Acknowledgments and Editor's Introduction.

The project's International Board of Consulting Editors, chaired by Smelser and Dr Peter Marsden of Harvard University, was formed late in 2011 as a 'sounding board' to be used by the Area and Section Editors in searching for topics and authors and to help push for greater internationalism in our coverage. As it turned out, several members of this Board also stepped up to write entries in their areas of expertise. The composition of this Board and the affiliations of the consulting editors (as they were when the Board was first formed, not necessarily as they are today) are as follows: Neil J. Smelser, *University of California, USA*; Peter V. Marsden, *Harvard University, USA*; Ronald F. Abler, *International Geographical Union, USA*; John Bacon-Shone, *University of Hong Kong, China*; Roberto Briceño-León, *Universidad Central de Venezuela, Venezuela*; Roel Bosker, *Rijksuniversiteit Groningen, The Netherlands*; Michael Burawoy, *University of California, Berkeley, USA*; Nestor T. Castro, *University of the Philippines, Philippines*; Dalton Conley, *New York University, USA*; Freek Cronjé, *North West University, South Africa*; Scott Davies, *McMaster University, Canada*; Abdul Rahman Haji Embong, *Malaysian Social Science Association, Malaysia*; Joan-Maria Esteban, *Barcelona Graduate School of Economics, Spain*; Robert S. Feldman, *University of Massachusetts, USA*; Sari Hanafi, *American University of Beirut, Lebanon*; Gudmund Hernes, *Norwegian Business School, Norway*; Sheila Jasanoff, *Harvard University, USA*; Tim Jensen, *University of Southern Denmark, Denmark*; Colin Jones, *University of London, UK*; Nadezhda Lebedeva, *Higher School of Economics; and National Research University, Russia*; Miklós Lévay, *Eötvös Lorand University, Hungary*; Dinka Marinovic Jerolimov, *Institute for Social Research, Croatia*; Laurie M. Joyner, *Rollins College, USA*; Ferenc Kiefer, *Hungarian Academy of Sciences, Hungary*; Pan Suk Kim, *Yonsei University, South Korea*; Katsuya Kodama, *International Peace Research Association; and Mie University, Japan*; Allan Lavell, *Facultad Latinoamericana de Ciencias Sociales (FLACSO), Costa Rica*; Jake Lynch, *University of Sydney, Australia*; Cecilia Mabragana, *Consejo Nacional de Investigaciones Cientificas y Tecnicas (CONICET), Argentina*; William McBride, *Purdue University, USA*; Ishwar Modi, *University of Rajasthan, India*; Leonardo Morlino, *School of Government, Italy*; Melvin L. Oliver, *University of California, USA*; Angela M. O'Rand, *Duke University, USA*; Kenneth Prewitt, *Columbia University, USA*; Thilo Rehren, *University College London Qatar, Qatar*; Colette Sabatier, *Université Victor Segalen, France*; Philip Schofield, *University College, UK*; Rainer K. Silbereisen, *University of Jena, Germany*; Chamhuri bin Siwar, *National University of Malaysia, Malaysia*; Tom W. Smith, *World Association for Public Opinion Research, USA*; Catalina Smulovitz, *Universidad Torcuato Di Tella Miñones, Argentina*; Philip Spinhoven, *Leiden University, The Netherlands*; Sukhadeo Thorat, *Indian Council of Social Science Research, India*; Nigel Thrift, *University of Warwick, UK*; John R. Townshend, *University of Maryland, USA*; Gisèle Yasmeen, *Social Sciences and Humanities Research Council of Canada, Canada*.

Searching for an editorial team to represent every social science discipline and every region of the globe quickly exposed the deficiencies in my personal network, so I am indebted to a very large number of scholars around the world for calling names of prospects to my attention, allowing me to drop their names in the recruitment effort, or otherwise helping me find people with the expertise and commitment required for the job. In most cases, this is a list of people who were invited onto the editorial team in some capacity,

demurred, but made valuable suggestions about others to contact. In several cases, people are listed because they engaged me in intellectual discussions about the structure, format, and even advisability of this work, or simply replied to a cold-call e-mail in pleasant, kind, helpful, or informative ways. Again ignoring the risk of omission, my sincere personal thanks to those named below for their contributions large and small to the final product:

Doug Anderton, Juri Allik, George Armelagos, Susan Ayers, Amanda Baumle, Janeen Baxter, Jess ben-Habib, Joao Biehl, David Blanchflower, Hans-Peter Blossfeld, Jason Boardman, Dorret Boomsma, Roel Bosker, Henry Brady, Martin Bulmer, Craig Calhoun, Miguel Centeno, William Cockerham, Mark Nathan Cohen, Amelie Constant, Simon Cottle, Connie Citro, Eileen Crimmons, James Curran, Scott Davies, Donatella Della Porta, George Downs, Francis Dodoo, David Dozois, Sonja Drobnick, Jaap Dronkers, John Dryzek, Riley Dunlap, Lauren Edelman, David Elesh, Paula England, Nancy Eisenberg, Geoffrey Evans, Miriam Faust, Robert Feenstra, Marcus Feldman, Stanley Feldman, Ronald Fischer, James Fowler, Jeremy Freese, Angela D. Friederici, Michael Frumpkin, Masahisa Fujita, Nicole M. Gage, Nancy Gallini, Rosemary Gartner, Morton Ann Gernsbacher, Robert Goodin, John Grattan, Lance Gravlee, David Greenberg, Wendy Griswold, Melanie Guldi, Monica Das Gupta, Peter Hatemi, Robert Haveman, Karen Heimer, John Hibbing, Sarah Blaffer Hrdy, Sheila Jasanoff, Kelly Kadera, Cigdem Kagitcibasi, David Kavanaugh, Roger Keil, Byungkook Kim, Rob Kitchin, Jack Knight, Lyle Konigsberg, Candace Kruttschnitt, Helen Ladd, Phillip Lane, Graeme Lang, Janet Lauritsen, Ashley Leeds, Evelyn Lehrer, Richard Lerner, David Lewis, Tim Liao, Tom Linneman, Norman Long, Karen Lyons, Ruth Mace, Gary Marks, Herbert Marsh, Karl-Ulrich Mayer, Lorraine Mazerolle, Rose McDermott, Susan Michie, Harry Minas, Peter Miller, S. Phillip Morgan, Victor Nee, Vin-Kim Nguyen, Paul Nieuwbeerta, Helga Nowotny, Howard Nusbaum, Claus Offe, Thomas Ollendick, Joan Orme, Dennis O'Rourke, Michael Overington, Catherine Panter-Brick, Susan Parnell, Deborah M. Pearsall, Gerard Pfann, Jon Pierre, Mike Ping, Jennifer Platt, Ken Prewitt, Cathy Price, Jill Quadnagno, Charles Ragin, Thilo Rehren, Ben Rosamond, Bo Rothstein, Beth Rubin, Heinrich Sauer, Peer Scheepers, Ralf Schwarzer, Moshe Semyonov, Michael Shanahan, Sara Shostak, Alan Sica, Rainer K. Silbereisen, Beth Simmons, Catalina Smulovitz, Michael Sobel, Diane Stone, Jill Stephenson, Rafe Stolzenberg, Miron Straf, Richard Swedberg, Alan C. Swedlund, Sidney Tarrow, Jacques-Francoise Thisse, Stefan Timmermans, Florencia Torche, Erik Tsang, Judy Treas, Billie Turner, Cees van der Eijk, Paul van Lange, James Vaupel, Karin Wahl-Jorgensen, Mitchell G. Weiss, Neil Whitehead, Pamela Wilcox, Bjorn Wittrock, Cornelia Woll, Gisele Yasmeen, and Barbie Zelizer.

Gratitude is owed as well to the many colleagues at Elsevier who contributed to the production of this volume. My first debt is to Claire Byrne, the project's Content Project Manager and the head of the Major Reference Works (MRW) team that managed the day-to-day *Sturm und Drang* of the project: aggrieved, confused, or delinquent authors, missed deadlines, testy and intransigent editors, and the often-maddening work style of the Editor in Chief. I am sure there were days when Claire wanted to tear her hair out, but to external appearances, she was an island of calm in a sea of turmoil. She was also exceptionally good at her job.

Claire's MRW team comprised Richard Berryman, Will Bowden-Green, Esmond Collins, Mark Harper, Sam Mahfoudh, Mike Nicholls, Gemma Tomalin, Joanne Williams, and Marise Willis. No matter what issue or problem I faced, one of these fine, capable people was always available to step up with a solution, invariably offered in a spirit of cooperation and good cheer. They have been to IESBS 2/e what tech support is to the modern computerized office. Getting this work completed without their help is inconceivable.

Thanks also to the succession of Elsevier's Acquisitions Editors who managed the finances and internal politics of the project: to Scott Bentley, whose gentle suasions pulled me into the project in the beginning; to Karen Maloney and Peter Labella who ran the show in the middle period; and to Lisa Tickner who was in charge at the very end. These are the people on the front line in the endless war between the publisher, who wants things done now and at minimal expense, and the Editor in Chief, who was always asking for more time and more money. The many dozens of amicable compromises necessary to bring the project to completion were all ably negotiated by Scott, Karen, Peter, and Lisa, and for that, I am grateful indeed.

The University of Central Florida and its Department of Sociology have provided a congenial home for the project. My thanks in particular to Dean Michael Johnson; to the current and former chairs of my department, Jana L. Jasinski and Libby Mustaine; to my faculty colleagues Liz Grauerholz, Phillip 'Hutch' Pollock, Bruce Wilson, Melanie Guldi, Stacy Barber, Tosha Dupras, and John Schultz; and to current and former graduate students Thomas Hall, Sara Strickhouser, Betsy Swart, Jordana Navarro, Marie Gualtieri, Shannon Simone, and Shannon Frey.

And most of all, my sincere thanks to the many thousands of authors whose work this is. When comparing the quality of the work contained within these pages to the authors' honoraria, it is obvious that IESBS 2/e is an act of collective charity by our authors to the disciplines they represent. It is my pleasure to thank our authors on behalf of the global social science community.

James D. Wright

GUIDE TO USING THE ENCYCLOPEDIA

Structure of the Encyclopedia

The material in the Encyclopedia is arranged as a series of articles in alphabetical order.

There are four features to help you easily find the topic you are interested in an alphabetical contents list, cross-references to other relevant articles within each article, subject classification index, and a full subject index.

1. Alphabetical Contents List

The alphabetical contents list, which appears at the front of each volume, lists the articles in the order that they appear in that volume of the Encyclopedia. It includes both the volume number and the page number of each article.

2. Cross-references

All of the articles in the Encyclopedia have been cross-referenced. The cross-references, which appear at the end of an article as a See also list, serve three different functions:

a. To draw the reader's attention to related materials in other articles.
b. To indicate material that broadens and extends the scope of the article.
c. To indicate material that covers a topic in more depth.

3. Subject Classification Index

This index appears in Volume 26 and groups articles under subject headings that reflect the broad themes of Social and Behavioral Sciences. This index is useful for making quick connections between articles and locating the relevant article for a topic that is covered in more than one article. Under some section headings, you will find subheadings, if it is appropriate for the articles in a subject area to be grouped into more specific subareas.

4. Contributors

At the start of each volume, there is list of the authors who contributed to that volume.

5. Index

The index appears in Volume 26. The index includes page numbers for quick reference to the information you are looking for. The index articles differentiate between references to whole article, a part of an article, and a table or figure.

Abstract

This article deals with defense and security, mainly from an economic point of view. It discusses some preliminary conceptual and methodological problems, explains the specific difficulties related to statistical data sources on military spending, and presents a historical contextualization of the theoretical debates. It wonders if defense is a public good and why the army tends to be privatized. Then it examines the effects of defense spending within the neoclassical mainstream, as well as economic studies on defense at the margins of this current. Finally, it moves toward heterodox interpretations in alternative schools of economic thought. It concludes that it is impossible to build a defense and security economics without politics.

Preliminary Conceptual and Methodological Problems

Generally regarded as the sovereign function par excellence, defense is a very special category of public expenditure. A study whose purpose is evaluating military spending in an economy must specify the contours of the diverse phenomena to be investigated and clarify the issues of definition and measurement of these expenditures. It would seem reasonable to define military spending as being the set of human and material resources devoted by a state to its defense and intended to guarantee its national independence, the integrity of its territory and, where appropriate, the respect of the international treaties binding the country to foreign states. This first definition, however, which gives primacy to relations between states and the classic conception of 'war' in the study of conflict in international relations, tends to underestimate the interweaving of internal and international conflicts, in their unstable and constantly evolving interdependence.

Under these circumstances, it would be appropriate to extend the concept of military spending to include all or part of the resources employed by a state to maintain internal security and public order. Actions to preserve order, performed by distinct state forces, justified by reason of state and occurring in extremely varied political contexts, appear difficult to separate from national defense operations in the strict sense. The nature of these actions is often identical and the objective remains the same: to ensure the proper functioning of a nation's society and economy, or basically to guarantee its survival, identity, and power. This broader interpretation thus corresponds to a perception of the state, responsible for allocations of national resources, as a producer of security and *de facto* public goods involving constraint, ensuring the cohesion of social structures, creating the conditions for the continuity and stability of economic life, and guaranteeing the maintenance of an institutional framework for activity.

The defense budget is not necessarily an appropriate indication of a country's real military effort. In some countries, the Ministry of Defense in fact assumes functions that by nature belong primarily to the civilian sector. Conversely, there may be public expenditure from the budgets of civilian ministries, which is mainly for military purposes or which partially benefits the armed forces. In the modern world, there is a growing difficulty of distinguishing between the strictly military and civilian functions of the state. This is the case of 'special activities,' such as drone operations or cyber-attacks.

Problems Related to Statistical Data Sources

Among the most delicate problems to be solved is the determination of the conditions of international comparability of defense spending. It is related to structural elements specific to each country (e.g., type of economy, pricing system practiced), deflators (i.e., the method of deflating time series), or conversion factors (exchange rate used). Here, the methodological difficulties are numerous and highlight the secret nature of such budgets. In addition, there are some specifically statistical complexities, for example, double accounting, removing costs from the central budget, foreign exchange manipulations, calculations of debts associated with military spending, and aggregation methods (Herrera, 1994).

A thorough review of the main statistical data sources that are of better quality than the 'primary' ones (the latter being those issued by the country's central authorities themselves) reveals some shortcomings. We can mention those in relation to the retention of information by the governments and the resulting widespread (legitimate?) opacity existing in this area, and those linked to international balances of power that operate to the detriment of the Southern and Eastern developing countries. Indeed, a few Northern countries occupy dominant positions within the international statistical administrations, and particularly the United Nations (UN, 2013) and the International Monetary Fund (IMF, various years). Frequently, their intelligence services directly support the collection and treatment of indicators, such as in the case of the Central Intelligence Agency (CIA, 2013) and, formerly, the US Arms Control and Disarmament Agency for the United States and the International Institute of Strategic Studies (IISS, 2013) for the United Kingdom.

Despite the well-known experience and excellence of their researchers, the few independent observatories, especially the Stockholm International Peace Research Institute (SIPRI, 2013), have neither the financial resources nor the institutional power to constitute comprehensive and reliable sources of alternative information.

These limitations, greater or lesser depending on the various institutions, prevent this type of research from relying on a single database. The necessary information may be published in national budgetary and fiscal documents or it may be published in the reports disseminated by specialized international organizations, like the United Nations Institute for Disarmament Research (UNIDIR, 2009). Military spending can occur in a wide variety of different parts of the state, and can be included in accounting lines destined for very different purposes.

Historical Contextualization of the Debates

Moreover, it is important to contextualize the current theoretical and empirical debates on the role of defense in the economy. At the worldwide level, military spending grew almost exponentially throughout the twentieth century until the beginning of its last decade. Since the early 1990s, the renewed interest in such issues from authors belonging to the present mainstream (i.e., neoclassical economics) was decisively driven by concerted research programs of major international organizations: IMF, World Bank, Organisation for Economic Co-operation and Development, etc. Mainly oriented toward studying the economic effects of resource reallocation raised by the end of the Cold War and the so-called peace dividends, these programs have coincided – not by accident – with the closure of a series of studies previously carried out on the Third World countries' external debt, whose main policy conclusions were to explain the latter not by the dysfunctioning of the global economic and financial order, but rather by the 'mismanagement' of public finances in these countries. This opened the way to the requirement of 'good governance,' a concept originally developed by the IMF and applied to all aspects of public affairs, including the combat against the financing of terrorism after the 11 September attacks (IMF, 2003).

The pressure exerted on public budgets in the countries of the South (and the East, following the Soviet bloc's collapse, the end of the 'arms race' with the United States, and the launch of 'shock therapy' transitions) then justified recommendations for defense spending reductions and military industries conversions. These changes implied, more often than not, fiscal trade-offs that resulted in cuts in public spending, especially for social purposes, to ultimately constitute the surpluses needed to continuously repay external debt services.

The combined logics of unbalanced disarmament (ensuring the United States its advance in armaments) and accelerated liberalization (with state-owned enterprises' privatization and flexibilization) cumulated their negative impacts and often led to more human insecurity (Mushakoji, 2008). Some countries under structural adjustment even experienced a 'scissors effect' characterized by a drop in defense spending and a simultaneous increase in police expenditures devoted to internal security and public order, and turned against an enemy that is not abroad.

Such reductions in military spending thus allowed the opening of new fiscal margins of maneuver to secure the noninterruption of debt-related transfers to Northern private creditors, along with the opportunity to induce a disarmament of regional powers in the emerging South (especially China), at the very moment when the unipolar hegemony of the United States began.

Is Defense a Public Good?

As in all economic theory, defense economics is currently dominated by the neoclassical mainstream. Its basic goal is to analyze social phenomena exclusively from the behavior of individual agents. In such a theoretical framework, defense represents a typical example of a 'public good,' whose characteristics would theoretically justify the intervention of the state. In neoclassical modeling, the goods that are produced by markets are generally destined for private use, and the interdependencies between individuals are (almost exclusively) mediated by the price system. Public goods can be distinguished from such market goods by the fact that they are subject to a collective consumption, which is not shared but equal for each agent, and benefits all of them – without any access exclusion through the prices. By their nature, these goods cannot be produced and allocated by markets, since price mechanisms affecting rationing of limited goods do not function as usual. In these conditions, neoclassical theory admits that their production can be entrusted to the state, which provides such public goods to the community by levying a tax to finance the associated costs.

Consequently, the justification for the production of collective goods by the public sector lies in the admitted inability of markets to provide them. Two explanations are put forward. First, if the consumption of these goods is not divisible, and if their market price is considered to be zero, private enterprises will have no incentive to produce them. Second, the impossibility of exclusion will lead agents not to reveal their true preferences in order to lower their contributions to paying for them. A problem of free riders exists where agents take advantage of honestly revealed preferences (thus also appropriate payments) of others by falsely underreporting their preferences, and hence underpaying. The result is a risk of a bias in favor of the undersupply of the public good (Stiglitz, 1988).

The main characteristic of defense that makes it a public good is that its supply is indivisible, like the state that supplies it. The indivisibility of its supply, which connects to the concept of 'increasing returns' that potentially can lead to monopolistic market structures that could justify the intervention of the state, is coupled with an indivisibility of use. It is not possible to reserve the exclusive use of this good to some individuals, since every citizen enjoys a right of free access and cannot be denied this protection. Each individual is intended to consume the public good, not because its provision is determined by his/her own decision, but because defense is fully available to the entire community, with a requirement of its use. Furthermore, the addition of a new individual consumer does not alter either the cost of national defense or the level of consumption by the other agents, since all of them consume the good 'completely,' and without rivalry (Samuelson, 1983).

Thus, the neoclassical authors generally admit the state's intervention in the field of defense for reasons that they consider to be less political, even if it is a more 'sovereign function' than economic. Indeed, in the presence of such a public good that markets are unable to produce and allocate

by a standard price system, the state alone is able to ensure the optimal market equilibrium for the entire society. This is a brief presentation in general terms of the academic consensus that exists on this issue in mainstream economics today.

Privatizing the Army?

One of the major difficulties in applying neoclassical public economics to defense, however, comes from the fact that this field combines several types of market imperfections. In order to get an 'optimal' expenditure by the state for this good, corresponding to a level that allows the individuals' willingness to pay to equal the cost of its provision, it is still necessary that the size and the composition of public budgets, as well as the technical characteristics and the fiscal costs associated with defense and other public services, be known by the consumers. Nevertheless, the agents generally face barriers to access to the information needed to measure the exact impact of military spending, especially on their individual well-being, or on the level of homeland security, which determines, among others, the social utility of defense. Therefore, this problem of information asymmetry, related to the confidential nature of the statistical data on military activities, prevents optimal public choices and the associated procedures of intrabudgetary allocation of resources. An additional difficulty stems from the dichotomous and atypical nature of the public good of defense. The latter increases the security, and the level of social utility, of the country that instigates it. But at the same time, internationally it reduces the security level of the foreign countries that are viewed as potential enemies in a noncooperative framework. As a result, the positive consequences generated by the military spending of a country on its national security can be globally offset (and more) by the negative externalities they cause for the agents of the foreign countries.

Some ultraliberal economists have challenged the public good character of defense. Faced with market failures, highlighted by the neoclassical theory itself, the public choice school has never stopped asserting that the functioning of market mechanisms, even when imperfect, remains systematically preferable to the defects of the state's intervention, which can mask individual preferences under the discourse of 'general interest.' Such authors, who come from the 'right' of the mainstream and use utilitarian approaches, assert that state intervention may generate adverse effects. These include pricing practices that are deemed suboptimal, the government's inefficiencies and behaviors that would not get the necessary information to effectively control natural monopolies, the nonappropriability of profits (thereby destroying managerial motivation and incentive), the risks of 'bureaucratic drift,' and eventual abuses of dominant position (Buchanan and Musgrave, 1999). Under these conditions, they wonder why a US citizen, or so-called consumer-taxpayer, living in Seattle or in Washington, DC, for example, would agree to pay a tax whose purpose is to finance the protection of the border of the United States with Mexico? According to them, the corresponding taxation burden should be borne only by the inhabitants of the concerned federal states, from Texas to California.

On the basis of extreme antistate positions, completely in favor of private property and free trade, some 'libertarian' theoreticians have gone so far as to recommend the privatization of the army (Friedman, 1973). For them, defense should be submitted to the laws of competition, like any other private good. There would be markets where enterprises (i.e., private military companies) would offer the goods and services that have been provided so far by the state, and in which agents would 'freely' select according to their security needs and to a rational quality-price calculus, by performing a standard cost-benefit analysis (Squire and van der Tak, 1975). Although these (quite provocative) proposals remain a minority within the theoretical debates, they have come to significantly influence real political practice, and even when their supporters are often firmly against war, because here the main issue is still the role of the state. The result is that while defense is still more often than not conceived of as a 'public good' in theory, it is widely privatized in practice. Did the neoliberal waves associated with Reaganomics not prompt the US government to begin outsourcing defense-related activities already in the early 1980s, a practice that has been continually extended since then?

The Effects of Defense Spending within the Neoclassical Mainstream

Defense economics is the subject of numerous and increasingly technical contributions due to leading mainstream authors (Intriligator, 1990; Arrow, 1992; for example, and even Sen, 1992). Paradoxically, these studies have failed so far to reach clear and sure conclusions.

To begin with, the debate on the externalities of military research and development (R&D) remains highly controversial among neoclassical economists. Many modeled or econometric studies evaluating the effects of military R&D show that a diversion of resources to defense is costly in terms of production. Here various justifications are given: military and civilian R&D would use similar resources, which implies crowding-out effects; the inelasticity of human capital supply would pressure upward R&D input prices; negative price elasticity of demand for inputs in this sector would exert a disincentive to private investment in R&D, etc. But these arguments are disputed and other authors have stated that technical progress incorporated into military equipment has a stimulating impact on private investment. Thus, the eventual tradeoffs are not convincingly demonstrated.

A consensus seems, however, to emerge in the mainstream around the idea that the contribution of military R&D to total factor productivity tends to decrease over time. Often assimilated to externalities, the technological spillovers from defense to civilian sectors (through transfers of innovative products/processes, commercial implementations, organizational and informational effects, and so on), which characterized the post-World War II (WWII) period, may be less important today. Some even believe that at present the net flow of scientific knowledge is reversed and that it is mainly directed from civilian R&D to defense. Under these conditions, the resource diversion to the strategic security of a country could deteriorate its 'economic security' by reducing technical progress in export sectors, thus productivity growth and competitiveness. Such questions are very difficult to solve from the mainstream's

point of view, especially as the effects of military R&D on the economy are contradictory according to the data, samples, specifications, or methodologies that are used. As a consequence, more detailed analyses about dual technologies led on a case-by-case basis and both intra- and intersectorally could be advocated.

The results of empirical studies treating defense as a public good also arouse controversies. The impact of military spending on total factor productivity or gross domestic product (GDP) growth rate is sometimes found to be nonsignificant, by Aschauer (1989) and Barro (1991), for example, but negative by many others, directly or not, through effects on investment, human capital accumulation, or international trade due to the opacity of import procedures or trade restrictions. Some authors, such as Landau (1993), tested a hypothesis of a nonlinear influence of defense on growth, by combining positive effects (enhancing security or incentive to effectiveness of public policies facing external threat) and negative ones (resource diversion from productive uses) and using a quadratic functional form between growth and defense. Estimates would confirm such a nonlinearity: the coefficients of military burden appear positive for its simple value and negative for its squared value. Increases in defense budgets would thus be associated with faster growth up to an optimum, but slower beyond. Deger (1986) argued that the sign and magnitude of the impact of defense would depend on per capita income: in poor countries, military spending would promote growth by their modernizing influence; the relationship is reversed for middle-income countries, where the crowding out of investment would dominate; and when per capita income rises, the impact would be positive again, thanks to technological spillovers. Obviously, the debate remains open.

Derived from multisectoral representations of factorial contributions to growth, supply models with externalities have specified transmission channels of the effects of military spending on the economy (Biswas and Ram, 1986). Growth engines are analyzed in a framework that allows one to decompose and to estimate separately the impact of military spending in two effects: the first one measures intersectoral differentials of marginal factorial productivity; the other captures the external effects of defense disseminated to the private sector. Nevertheless, most econometric estimates using such a methodology give disappointing results, often revealing no significant impact of military spending on GDP growth. These mitigated findings could be partly explained by the persistence of unresolved technical difficulties due to multicollinearity between the variables tested.

In addition, typically neoclassical computable general equilibrium models have been used in this field. Their simulations often exhibit investment and GDP gains consecutive to reduced military spending. However, this type of formalization is strongly questionable. Studying the multifaceted effects of defense requires analyzing more specifically the implications of the accretion of various forms of capital. The enlargement of the approach to long-term growth allowed one to use more sophisticated modeling than econometric specifications, and to capture truly dynamic effects of these expenditures. Endogenous growth theory has placed emphasis on the role of the accumulation of human capital and/or infrastructure in determining the growth rate in the long run. Here, choices of economic policy related to the structure of public budgets may be important in explaining the economies' growth performances, by trade-offs operating between military spending and growth engines. Among the modeled positive effects emanating from the defense sector, one can mention, in the production function, the increase in total factor productivity caused by the influence of military capital on technical progress and, in the social utility function, a strengthening of security, and thereby an improved well-being. The possible negative effects include the mobilization of skilled workers by defense, which reduces human capital available for productive sectors, or fiscal trade-offs to the detriment of other public spending (such as education). Endogenous growth modeling is, however, subject to a series of criticisms (Herrera, 2011).

A deficiency of many neoclassical models is the lack of consideration of security indicators, which prohibits thinking in strategic and geopolitical terms. The analysis of the links between growth and security, resulting particularly in deepening interactions between Pareto optimality and Nash equilibrium can then lead into the field of game theory, a field of mathematical expression (Intriligator and Brito, 1976). But here again, the attempts of incorporating military variables in the neoclassical paradigm, which have certainly brought some very interesting insights, remain often contradictory, uncertain, or unsuccessful (Herrera, 2010).

At the Margins of the Mainstream

Nevertheless, economic theory has experienced consistent developments near or even outside the margins of the mainstream. Such is the case with the interindustry input–output models. Distinct from the standard neoclassical analysis, the latter provide original tools – relevant in our opinion– to measure macroscopic effects of changes in defense spending at the national, regional, and international levels, taking into account resource allocations between civilian and military sectors in disaggregated frameworks. Such a methodology, using projections on short, medium, or long terms, has proved especially suitable for assessing the effects of fiscal choices made in connection with various disarmament plans. Input–output analyses were repeatedly employed by Leontief and his teams to study the consequences of cuts in defense budgets on the US economy, and to simulate scenarios of regional and global disarmament (Leontief and Duchin, 1983). At the margins of the neoclassical mainstream, macroeconomic demand models, which use an equation of national income balance from Keynesian inspiration, postulate a negative impact of military burden on demand – via the multiplier – by distinguishing differentiated influences on nonmilitary public spending and on components of the private sector absorption (Smith, 1977). This approach has the advantage of providing a framework that identifies crowding-out effects following defense spending shocks that are potentially detrimental to consumption, investment, or exports, and may adversely affect short-term activity, in particular through underemployment. However, these models are insufficient: they do not capture the impact of the military sector on the accumulation dynamics; they do not distinguish with the necessary precision effects

operating in long or short term, nor the different contractions of investment (directly productive) or consumption (unproductive); and finally, they do not really clarify the atypical nature of defense, which has complex relations with the rest of the economy, distinct from those associated with other public spending (Benoit, 1973). Moreover, empirical studies based on such specifications remain in a state of uncertainty as to which category of demand may suffer the most from these crowding-out effects (Hartley and Sandler, 2007).

Under these conditions, a path followed by authors of the Keynesian-neoclassical synthesis has been to consider, in a perspective of longer term, a supply component, whose role is frequently neglected in most Keynesian models. Formally speaking, taking into account supply requires using a standard production function. The introduction of military spending in a multisectoral framework with differentiated production functions can consider a final good of the private sector derived from a technology combining usual factors (capital and labor), plus a military public good, to be interpreted as an externality. But it can also go through the disaggregation of the capital stock into civilian and military components in order to estimate econometrically the elasticity of the product to the military capital and the contribution of this stock to growth. However, the economically unproductive (or not directly productive) character of defense still makes this kind of specification difficult to sustain.

Consequently, some economists are led to simultaneously incorporate supply and demand aspects in dynamic equations, which allows them to deduce from the national income balance an expression of capital accumulation and a production function where efficient labor and effectively used capital (with an efficiency parameter characterizing capital underutilization) enter. As growth in the steady state is determined by demographic and technological evolution (assumed exogenous here), military spending has no effect on it in the long term, except if a potential effect of these expenditures on technical progress is considered. But their impact is perceptible on the transitional path leading to the steady state. Such models make the direct impacts of defense spending conceivable: negative supply-side effects on private capital accretion, through the savings rate, by crowding out investment; but positive demand-side effects on the utilization rate of capital, through the mobilization of productive capacities in the short term (Deger and Sen, 1995). More indirect influences may also be highlighted, including on the private sector's propensity to save, the share of civilian expenditures in public budgets, the capital–output ratio, or the balance of payments. Adverse effects may be amplified if, for example, the increase in the military burden is covered by cuts in social expenditures.

Toward Alternative Interpretations

In the manufacture of armament equipment, the economic weight of the private enterprises in the military–industrial complex was already considerable at the end of WWII. In the 1950s, US President Dwight D. Eisenhower felt compelled to warn his fellow citizens against the increasing threat posed by the collusion of interests of this industry, big business, and the army (see Eisenhower's Farewell Address to the Nation on 17 January 1961). During the conflict in Vietnam, many private big corporations were integrated into the war effort; among them were DynCorp, Halliburton, Vinnell, Lockheed Martin, and General Dynamics. Today, the main suppliers of the US Department of Defense are transnational firms involved in shipbuilding, aerospace, and computers, whose military contracts drain off astronomical amounts of federal dollars. Private military companies also provide to the federal states, international institutions, nongovernmental organizations, and other private entities. They provide a very large range of technical services aimed at assisting or supplementing regular armed forces in the protection of strategic sites (military bases, oil fields, mines, nuclear facilities, etc.), and in building, logistics, military training, intelligence, public relations, and the provision of specialized staff (consultants, bodyguards, mercenaries directly involved in combats, etc.).

During the period of the Cold War, the expansion of the productive forces in the United States was partly driven by the 'arms race,' including the development of a number of important associated technological advances, such as computation systems, robots controlled by computers, and, more recently, the Internet. Nowadays, the US defense budget remains large, at nearly 5.0% of GDP and 45% of the world military expenditures. Moreover, the military–industrial complex continues to play a key role, but it now functions under the control of high finance. As a matter of fact, in the military sector in the 2000s, the share of the ownership capital held by institutional investors that were themselves controlled by the biggest financial oligopolies reached approximately 95% of the total assets of Lockheed Martin, 75% of those of General Dynamics, 65% of Boeing, and so on. A similar evolution occurred to the private military companies, with an increasing share of their capital falling under the thumb of high finance. Indeed, Military Professional Resources Inc. (MPRI) was bought by L-3 Communications, Vinnell by Carlyle, and DynCorp by Veritas.

At this stage, one may wonder whether crisis and war are intertwined. From a Marxist point of view, war would be economically integrated into the capitalist cycles as an extreme form of capital destruction (or devalorization). At the same time, and in a context of accentuation of the internal contradictions of capitalism, it would serve politically to reproduce the conditions for maintaining command by the dominant fractions of the ruling classes, that is to say, high finance, over the capitalist world system.

These observations revitalize theories of imperialism, for which the use of armed force is a strategy imposed by finance as the means of reproduction of its power, and where militarization is the essential modality of the existence of capitalism. In such a context, the role of the state becomes absolutely crucial to capital, since it is the state that goes to war on behalf of capital.

Military spending has become a major source of profit for the capitalists, in particular because it can transform productive capital – especially when it is financed by public debt – into fictitious capital. In addition, it should be observed that the wars in Afghanistan and Iraq were launched in a time of crisis (2001–03, as the years 1913 and 1938 were too); a crisis that emerged along with monetary policy changes occurred in connection with the worsening of the internal and external

deficits in the United States, partly because of the need to finance its war effort as a global hegemony.

The question then is whether the United States could revitalize capital accumulation in the center of the world system by wars. Some answer no, insofar as the destruction of (constant and variable) capital caused by these conflicts, which are dramatic for the countries that suffer from them, would be insufficient to promote a new long cycle of capital expansion in the United States, as was the case in the post-WWII period. Such wars would also be insufficient when one takes into account the associated effects of effective demand, mostly active in the short term, and the technological effects, which are positive only for the military–industrial sector. Insufficient, unless modern imperialist wars expand and become permanent.

Under these circumstances, it would definitively be hopeless to try to build, as the neoclassical mainstream is attempting, an 'economics of war,' or even a defense and security economics, without politics (Herrera, 2013).

Defiant Behavior During Adolescence across Cultures

Leslie Berntsen and Laura A Baker, University of Southern California, Los Angeles, CA, USA

Abstract

A review of cross-cultural studies of defiant and other deviant behavior during adolescence is provided. Race, ethnicity, and nationality are considered as possible aspects of culture. Although deviant behavior is relatively common in the United States and other Western cultures, there are variations across racial and ethnic groups. Cross-nationally, there is little variation across Western cultures, although deviance is somewhat less prevalent in nonindustrialized societies where children gain adult responsibilities immediately after puberty.

Adolescence has long been equated with defiant behavior. In *Rhetoric*, Aristotle declared youth to be as "heated by nature as drunken men by wine." In *Emile*, French Enlightenment philosopher Jean-Jacques Rousseau advised parents to "keep their hand[s] on the helm … [lest] all be lost." And, in 1904, G. Stanley Hall, the first president of the American Psychological Association, coined the now ubiquitous phrase "storm and stress" to refer to the characteristic turbulence of the teenage years. Adolescents, he believed, constituted a separate race that would be properly integrated into normal adult society in their own due time (Arnett, 1999: p. 317).

Hoping to challenge the popular conception that the 'omnipresent and obvious symptoms of unrest' widely observed during adolescence are simply 'characteristics of the period,' anthropologist Margaret Mead set sail for Samoa in 1926. After 2 years of living among young women on the island of Ta'u, she ultimately concluded that "adolescence represented no period of stress or crisis," largely due to the "general casualness of the whole society" (Mead, 1928: pp. 109, 137). Unlike contemporary American culture, authority was diffused over large families, young people could move from family to family within their villages, and girls had the socially sanctioned freedom to sexually experiment. In Samoa, the constraints of a society that demonizes adolescents were conspicuously absent.

In the years since its publication, *Coming of Age in Samoa* has been met with its fair share of controversy. Based on his own fieldwork in Samoa, one of Mead's most vocal critics, Derek Freeman (1983), claims that Mead had not only been deceived by her informants, but that she also deliberately fabricated evidence in support of her ideological leanings. More recently, other anthropologists have come to Mead's defense, claiming that Freeman's criticisms (1) lack ethnographic accuracy and (2) represent an unjustified attack on her reputation driven by his own personal beliefs (see Shankman, 2009). While we will not further discuss the Mead–Freeman debate in this article, we do acknowledge *Coming of Age in Samoa* as the first major work to challenge the universality of adolescent defiance, thus laying the theoretical groundwork for the future study of cross-cultural adolescent behavior.

Defiance as a Form of Deviance

In reviewing cross-cultural studies of defiant behavior, it is useful to consider defiance as a specific form of the more general category of antisocial or deviant behavior. In this article, we thus broadly define 'defiance' to also include various forms of deviant and antisocial behavior. For the sake of uniformity, we will refer to all of these behaviors as 'deviant' for the remainder of the article.

At its most basic level, deviance is principally characterized by a violation of social norms (see Franzese, 2009: pp. 6–7, for a review of contemporary sociological definitions). Since deviance is always defined in relation to a set of specific collective expectations, it is an inherently value-laden, context-dependent term. Beliefs and behaviors that might be viewed by one person as 'deviant' could easily be viewed as acceptable or even virtuous by another (Potter, 2011). In the United States, deviant behaviors that actively impinge upon the rights of others are diagnostically codified in the form of oppositional defiant disorder (ODD), conduct disorder (CD), and antisocial personality disorder (American Psychiatric Association, 2000). Many scholars have argued against the medicalization of deviance on the grounds that a diagnostic label can serve as a powerful tool of social and political control that can be used to pathologize behaviors that are more disagreeable than dangerous (see Conrad, 1992).

For example, during the Cold War, government officials in both China and the former Soviet Union imprisoned 'mentally ill' political and religious dissidents in asylums in order to suppress the opposition they deemed harmful to the rest of society (Bonnie, 2002). An in-depth analysis of how certain acts come to be regarded as deviant or whether they deserve to be considered deviant is outside of the purview of this article. Here, we limit our discussion to deviant behaviors (including defiance), widely associated with adolescence in the Western world. These include drug use and distribution, risky sexual behavior, generalized delinquent (including law-breaking) behavior, and aggression, all of which cause direct economic, emotional, or physical harm to oneself or others.

What Is Culture?

In order to understand how certain cultural factors might encourage or discourage deviant behavior during adolescence, we first must specify what we mean by culture. In the definition often referred to as the 'gold standard' among anthropologists, E.B. Tylor (1871: p. 1) defined culture as "that complex whole which includes knowledge, belief, art, morals, law, custom, and

any other capabilities acquired by man as a member of society." A century later, specifically applying the definition to the study of psychological processes, Marsella (1987: p. 381) proposed that culture also comprises any individual's "values, attitudes, beliefs, cognitive styles, and patterns of consciousness." Although preferred by scholars in different disciplines, both of these definitions converge on the idea that 'culture' cannot be neatly reduced to a single factor. Unfortunately, cross-cultural scientific research often disregards the notion of a 'complex whole' in favor of empirical simplicity. 'Culture' is frequently conflated with racial or ethnic categories, with national (or even continental) borders often used as a proxy for group membership. Although a common identity might be more likely to lead to shared experiences that contribute to common psychological development, an emphasis on group membership above all else can easily obscure within-group heterogeneity and draw misleading distinctions between individuals that actually share more similarities than differences (see Choudhury and Kirmayer, 2009). Not all of the research cited in this review was conducted with these principles in mind, so we urge readers to look beyond labels in order to understand the underlying processes – values, beliefs, practices, etc. – that constitute the ever-evolving notion of 'culture' and that might contribute to adolescent deviance.

With these definitions and concerns in mind, we review here studies investigating the differences in deviant behavior across groups pertaining to *race, ethnicity, and nationality*. We also discuss sociological theories that suggest differences across industrialized vs nonindustrialized societies, and individualism vs collectivism. Although gender and socioeconomic groups might well be considered as cultural entities, we have not reviewed these studies in this article, since they are described elsewhere.

Cross-National Differences

Mixed results emerge from the literature on cross-national differences in deviant behavior during adolescence. One meta-analysis of 25 cross-national studies conducted between 1997 and 2008 revealed that prevalence estimates of both ODD (0.6–11.0%) and CD (0.47–8.7%) did not differ as a function of geographic location (Canino et al., 2010). Rather, methodological differences between studies accounted for a greater proportion of the variability in prevalence rates. However, of the 25 studies that met criteria for inclusion in the final analysis, only four were conducted in non-Western countries (three in Asia and one in the Middle East). In their discussion, the authors note that differences between Western and non-Western countries might have emerged if more non-Western cultures were included in their analysis.

Findings from non-Western cultures do, in fact, suggest some cross-national differences in deviant behavior. Markedly lower rates of adolescent problem behavior (smoking, drinking, and general delinquency) have been found in China compared to the United States (Jessor et al., 2003). In observational studies of children in four non-Western cultures (American Samoa, Belize, Kenya, and Nepal), physical aggression was not an entirely common occurrence, comprising 10% of boys' and 6% of girls' social behavior (Munroe et al., 2000). However, aggressive acts were significantly more common among children in the two patrilineal societies (the Newars of Nepal and Logoli of Kenya) than those in the nonpatrilineal societies. Still other researchers have found adolescent deviance to be quite common in non-Western cultures. Among a random sample of male adolescents in Colombia, Pineda et al. (2006) observed prevalence estimates of CD to range from 10.5 to 35.5%, much higher than independent estimates in the United States (Hinshaw and Lee, 2003).

Despite differences in the incidence of adolescent deviance, it does seem that similar developmental processes are at play in discouraging such behaviors across national borders. Investigating the relationship between adolescent misconduct and the parent–child relationship in Hungary, the Netherlands, Switzerland, and the United States, Vazsonyi (2003) found parental closeness, support, and monitoring to independently predict adolescent problem behaviors (ranging from misbehaving in school to physical assault) in all four countries. Researchers have also found a similar protective relationship between parenting practices and deviant behavior (drug use, nonaggressive antisocial behavior, and physically aggressive antisocial behavior) among adolescents in Canada, France, and Italy (Claes et al., 2005).

In summary, the evidence for cross-national differences in deviant behavior during adolescence appears to be mixed. While few differences have been found between (mostly) Western cultures (Canino et al., 2010), some disparities are evident between Western and non-Western cultures, and when certain non-Western cultures are compared to one another. Rates of substance use and delinquency are lower in China but higher in Colombia compared to the United States, while aggression is not uncommon in other non-Western cultures (American Samoa, Belize, Nepal, and Kenya). Although these findings do not allow us to draw definitive conclusions about the worldwide distribution of adolescent deviance, they do lend support to Mead's initial observation that it is (in its many manifestations) far from a universal phenomenon.

Racial/Ethnic Differences in the United States

To explore whether adolescent deviance might be more consistent within a given country, we now turn to differences between racial and ethnic groups in the United States. Although criminal behavior can be a useful index of deviance, African and Hispanic Americans are disproportionately incarcerated relative to their Asian or European American counterparts (Glaze, 2011). Since there is growing evidence to suggest that these disparities can be largely attributed to racial profiling, aggressive police practices, targeted prosecutions, and sentencing biases (Gelman et al., 2007; Steffensmeier et al., 2006), it is especially crucial to look toward empirical studies that propose cogent explanations for specific differences in deviant behavior, rather than attempt to draw conclusions from crime statistics or any other purely observational data.

Using data from the National Longitudinal Study of Adolescent Health, Blum et al. (2000) found some evidence of racial differences in adolescent high-risk behaviors. Replicating

earlier findings, White adolescents were the most likely to use substances or attempt suicide, Black adolescents were the most likely to have already engaged in sexual intercourse, and Black and Hispanic adolescents together were more likely to participate in acts of violence than White adolescents. However, after controlling for gender, income, and family structure, race accounted for less than 10% of the variance in risk behaviors among both younger and older adolescents. That is, although racial differences were observed, race alone could not accurately predict the likelihood that any one person might engage in those behaviors. An additional study focusing solely on high-risk sexual behaviors during adolescence found similar results. Although higher levels of parental education, a two-parent family, and a European–American background were all independently negatively associated with risky behaviors, neither race nor socioeconomic status could fully explain the rates of pregnancy and sexually transmitted diseases observed in the sample (Santelli et al., 2000). These results further emphasize the heterogeneity that occurs within racial and ethnic groups in the United States, which ultimately should discourage their use as sole explanatory variables in scientific research.

Industrialized vs Nonindustrialized Societies

Contemporary research continues to validate Margaret Mead's assertion that adolescence is neither uniformly experienced nor defined. Schlegel and Barry (1991) have found the usual 'storm and stress' of adolescence to be far less frequent, if at all present, in nonindustrialized societies. Interestingly, many of these societies lack a specific word to describe the period between childhood and adulthood due to various cultural constraints. For some societies that are heavily agrarian, children might work directly alongside adults as soon as they are physically capable. In others, girls might be expected to bear their own children immediately after the onset of puberty. And, in perhaps the most drastic shift from childhood to adulthood, some children are involuntarily recruited to participate in armed conflict. Each of these cases leaves little, if any, room for the developmental middle ground that is adolescence (see Brown and Larson, 2002).

Individualism vs Collectivism

However, as previously mentioned, some industrialized societies (e.g., the United States and China) have been found to show markedly different levels of deviant behavior among adolescents (Jessor et al., 2003). In order to account for this difference, we now turn our attention to two distinct, heavily researched cultural typologies: individualism and collectivism. Much like the name suggests, individualism prioritizes the needs and desires of the individual over those of any given group. Individualists often have loosely defined, dynamic social relationships and generally prefer to exist autonomously of others' influence. In contrast, collectivists tend to define themselves by their interdependent relationships with friends, family, and society at large, placing great emphasis on group needs and social harmony (Markus and Kitayama, 1991; Triandis, 1995). Although collectivism is rooted in traditional Confucian values, it is certainly not geographically bound; collectivistic values have also been widely observed throughout Latin America, Africa, and South Asia (Triandis, 1989).

Might cross-cultural differences in deviant behavior during adolescence emerge as a consequence of different values between individualistic and collectivistic cultures? Tyson and Hubert (2012) have found that adolescents from Australia and various East Asian countries differ in the way they think about delinquent behaviors (e.g., theft, property damage, drug use, drunk driving, etc.). Although participants from both groups agreed which behaviors were more or less severe than others, Australian adolescents rated delinquent behaviors as significantly less wrong than their East Asian counterparts. Especially reflective of the collectivist emphasis on social harmony and deference to authority, 'shouting abuse at your parents' was the single item with the greatest difference between the two groups. Further, as East Asian participants aged, they perceived delinquency as less acceptable, while Australian participants showed no change or even perceived delinquent acts as more acceptable, depending on the specific behavior.

But do differences in beliefs necessarily map on to differences in behavior? One metaanalysis of 185 different cross-national comparisons found that aggression was significantly less frequent in cultures that value collectivist ideals, egalitarianism, and moral discipline (Bergeron and Schneider, 2005). However, this study is only an indirect measure of association between cultural values and aggression. As the authors acknowledge, national indices of values are very useful for understanding cross-national differences in behaviors, but they do little to help us understand how cultural factors might influence individual differences.

When study participants are asked to specifically report the extent to which they endorse individualism or collectivism, similar patterns of results emerge. In a mixed gender sample of Chinese adolescents, self-reported individualism positively predicted, and self-reported collectivism negatively predicted, peer and teacher ratings of both overt and relational aggression (Li et al., 2010). This pattern has also been found to extend to delinquency more generally. Among a sample of Chinese, Cambodian, Laotian, and Vietnamese youth, the frequency of self-reported delinquent behaviors was, again, directly related to individualism and inversely related to collectivism (Le and Stockdale, 2005).

Similar cultural values have been found to exert similar effects among non-Asian adolescents. In research examining the relationship between traditional Latino family values and externalizing behavior, German et al. (2009) found that Mexican–American adolescents with a heightened sense of familial obligation and emotional closeness to their family exhibited fewer externalizing conduct problems according to two independent teacher reports, even when they were exposed to deviant peers. However, a separate study revealed that Mexican adolescents who had acculturated to mainstream American culture reported engaging in more delinquent behaviors than those who had chosen to remain unacculturated, those who had very recently immigrated to the United

States, and White non-Hispanic adolescents (Fridrich and Flannery, 1995).

In short, a wide variety of deviant behaviors appear to be more reliably associated with broad sets of values than with race, ethnicity, or nationality, per se. Regardless of the specific name, belief systems that emphasize the responsibility of the individual to some larger collective entity (whether it be one's family or society at large) seem to protect against adolescent deviance.

Biological Explanations of Adolescence

When it comes to explaining the 'storm and stress' of contemporary Western adolescence, biological, value-free explanations reign supreme. In these accounts, deviant, risk-taking behaviors are framed as unfortunate, yet inevitable, consequences of the many neurodevelopmental changes that accompany puberty. Some of the most profound changes are related to the development of the prefrontal cortex. Often referred to as the brain's CEO, the prefrontal cortex is responsible for a variety of higher-order executive functions, including controlling one's impulses, initiating appropriate behaviors and inhibiting inappropriate behaviors, organizing complex information, making decisions, and empathizing with others. Clinical populations with prefrontal damage often show lapses in moral reasoning, an inability to anticipate future consequences, and an inability to inhibit inappropriate social behavior. In healthy individuals, the prefrontal cortex does not fully mature until the mid- to late 1920s. As it matures, the number of dopaminergic inputs to the region dramatically increases, a change reflected the newfound ability to control one's impulses and make more mature, reasoned decisions (see Weinberger et al., 2005, for a review). As a result, prefrontal deficits are widely cited as the sole underlying cause of adolescent 'storm and stress' (for reviews, see Blakemore and Choudhury, 2006; Casey et al., 2008; Nelson et al., 2005).

Challenges to the Storm and Stress Model

As Jeffrey Jensen Arnett (1999) suggests, the dominant 'storm and stress' model of adolescent deviance discounts individual differences in the adolescent experience within a given society, in addition to the differences observed between societies. Although the teenage years might be the most likely time for storm and stress to occur, not every teenager in the Western world experiences a similar period of angst, rebellion, and high-risk behavior. As a scientific category, adolescence represents the product of a very specific social and historical moment in time in which social Darwinism reflected the dominant ideology. Adolescents, in the view of early theorists like G. Stanley Hall, were simply not fit enough to survive (Choudhury, 2010). As a result of both intracultural differences in the normative adolescent experience as well as its history as a construct, some researchers argue that adolescence is a socially constructed, culture-bound syndrome that has been wrongly medicalized and used as a tool of social control (Hill and Fortenberry, 1992).

Culture and Biology: Mutually Constitutive

Clearly, the brain and the changes it undergoes "cannot be viewed separately from the material, historical, and social circumstances that produced it" (Lock and Nguyen, 2010: p. 109). Even so, it is important to note that the acknowledgment or appreciation of cultural differences does not require an outright repudiation of scientific evidence. As Davis and Morris (2007) argue, "the biological without the cultural, or the cultural without the biological, is doomed to be reductionist at best and inaccurate at worst" (p. 411). Neither a biological explanation of the 'storm and stress' model nor a purely descriptive account of cross-cultural variations is entirely correct. To get a more complete picture, we first need to understand how culture and biology might interact to give rise to psychological outcomes.

In a prime example of culture-gene coevolution at work, Chiao and Blizinsky (2010) found that individuals from collectivist cultures across 29 nations were more likely to carry the short (S) allele of the 5-HTTLPR serotonin transporter gene, which is associated with negative emotion and heightened anxiety. However, these same individuals were also less likely to suffer from mood or anxiety disorders. At first glance, these results seem paradoxical: How could a population with a heightened genetic risk for mood and anxiety disorders show decreased prevalence of those disorders? In their analysis, the authors argue that the collectivistic emphasis on social harmony lessens exposure to the types of chronic stress that put genetically susceptible individuals at risk of developing these conditions. That is, the cultural environment serves as a protective buffer against the harmful effects of various forms of psychopathology.

Conclusions and Future Directions

Deviance is clearly a multidimensional construct. Various forms of deviant behavior during adolescence have been observed in many locations and populations around the world, although there are notable differences and trends. First, adolescent deviance seems to be less common in nonindustrialized societies where children gain adult responsibilities immediately after puberty (see Brown and Larson, 2002). Among Western industrialized nations, there is little overall variability in the prevalence of deviant or antisocial behaviors. And within the United States, there appear to be negligible differences between racial and ethnic groups. Nonetheless, adolescent deviance is generally a common occurrence in the Western world. When compared to Western adolescents, those from non-Western (especially Asian) cultures show significantly lower levels of a wide variety of deviant behaviors. Some researchers suggest that adolescent 'storm and stress' arises as the result of brain development, while others believe that it might be most productively understood as a function of specific cultural constraints and belief systems. Although a single cause remains elusive, it is clear that both biological and cultural explanations are not only useful, but vitally necessary, to understand deviant adolescent behavior.

Defiant Behavior During Infancy and Early Childhood

Abstract

In this article, we trace normative and clinically significant trends in the development of oppositional, defiant, and aggressive behavior across infancy, toddlerhood, and the preschool years. Defiant, noncompliant, and aggressive behavior is relatively common between the ages of 2–5 years. These problems decline steadily as children develop age-appropriate skills for regulating negative emotions and behavioral impulses. However, some preschool-age children manifest severe behavior problems that persist across later childhood and adolescence. We identify features of early behavior problems that signal clinical relevance and link individual differences in early behavioral adjustment to child–environment transactions that reflect risky patterns of temperament and caregiving.

Learning to establish cooperative social relationships is a critical developmental task for preschool-age children. Getting along with others requires a complex array of skills, particularly sharing attention and play materials with others, inhibiting aggressive and destructive impulses, following directions, responding appropriately to requests, and delaying gratification of immediate desires. Young children who fail to master these challenges, especially those who show chronic high levels of 'externalizing' symptoms such as defiance and aggression, are at risk of later academic failure; conflicted relationships with parents, siblings, peers, and teachers; delinquency; and substance abuse (e.g., Broidy et al., 2003). However, defiant and aggressive behavior is common in early childhood, reflecting normal maturational variations in the development of self-regulatory competence, communication skills, and social understanding (Tremblay, 2010). To understand the significance of early externalizing behavior, we must differentiate children's struggles with normal maturational challenges from precursors of serious problems. In what follows, we examine evidence that helps us differentiate normative expressions of problem behavior from precursors of persistent and serious problems. Next, we define the clinical parameters of early aggressive and oppositional defiant behavior. Finally, we highlight known risk factors and processes associated with persistent early-onset disruptive behavior problems, with an eye on prevention.

Normative Developmental Trends in Early Aggression and Temper Loss

In this section, we trace the early developmental progression of key behavioral markers of early-onset disruptive behavior disorders: aggression, temper loss, and oppositional defiant behavior. Which behavioral patterns differentiate normative from high-risk problem behavior?

Aggression

Relatively little is known about the development of aggressive behavior in the first 2 years of life. Available studies indicate that coercive use of force and frank physical aggression are fairly common behavior in toddler-age children (Alink et al., 2006; Tremblay et al., 1999). For example, in a large longitudinal study of normally developing children in day care (Study of Early Child Care and Youth Development; NICHD ECRRN, 2004), mothers rated the frequency of children's physical aggression at ages 24, 36, and 56 months and through the early school-age years. The most frequent form of early aggression, hitting others, occurred in 70% of the sample at ages 2 and 3, but declined to 20% at ages 4 and 5 and to 12% in the third grade. Other forms of disruptive behavior (e.g., 'destroying others' things') also showed marked declines across the preschool- and early school-age years (NICHD ECCRN, 2004).

Thus, coercive–aggressive behavior is common in early toddlerhood and peaks between ages 2 and 3 years, declining rapidly across the preschool period. By the time children enter kindergarten, overt aggressive behavior is largely inhibited (Tremblay, 2010). However, these normative trends summarize average behavioral tendencies across large groups of children. *Individual differences* in early aggressive behavior remain moderately stable across the preschool to school transition (Keenan et al., 2011). That is, although normally expected levels of aggression decline with development, a child's position in relation to his/her peers is fairly stable, even across major developmental transitions. Moreover, a subgroup of preschool-age children continues to show high levels of problem behavior across the school-age years (e.g., Broidy et al., 2003; NICHD ECCRN, 2004).

Temper Loss and Oppositional Defiant Behavior

Displays of anger and frustration are common among toddlers and preschoolers. Full-blown tantrums appear by the first year after birth, peak around 20 months, then decline across the preschool years (Tremblay, 2010). How do parents discern whether their child's temper outbursts signal the development of serious and long-lasting problems? Several studies have shown that normative temper outbursts are less frequent and prolonged than clinically concerning outbursts, and tend to primarily occur in the home setting (Belden et al., 2008; Osterman and Bjorkqvist, 2010). In addition, there are

important qualitative differences between normative and clinically significant forms of temper loss. For example, hitting, kicking, and/or biting during the tantrum; having a tantrum with no clear precipitating frustration; having a tantrum with adults other than parents; and showing explosive and extreme anger during the tantrum were found to be relatively rare among preschool-age children (Wakschlag et al., 2012). These nonnormative temper loss behavior may indicate serious adjustment problems that persist across the transition to school.

Finally, oppositional behavior appears in the toddler period and is common during the preschool- and early school-age years. Typical problem behavior includes arguing back, refusing to comply with parents' requests, and testing the 'limits' of parental control. Oppositional defiant behavior declines in frequency across the primary grades, then increases again during the transition to puberty (Tremblay, 2010). Clinically significant manifestations of oppositional behavior are marked by the frequency, severity, and persistence of the child's oppositional behavior in relation to normally developing age peers (Keenan and Wakschlag, 2000). Oppositional defiant disorder (ODD) is the most common disruptive behavior disorder in young children. The core feature of ODD is a chronic pattern of negativistic, defiant, disobedient behavior toward authority figures, usually the child's parents (American Psychiatric Association, 2013). Children with ODD tend to show frequent temper tantrums, often refuse to comply with their parent's requests, may make deliberate attempts to annoy others, and often react to frustration with hostility or aggression.

Preschoolers with ODD are at elevated risk for developing conduct disorder (CD) in later childhood. For example, approximately 30–50% of children with diagnoses of ODD progress to later CD (Waldman and Lahey, 2013). CD is defined by a chronic, age-inappropriate pattern of behavior that violates the rights of others and breaks major social rules (American Psychiatric Association, 2013). Children with CD often behave aggressively toward people and animals: they may initiate frequent fights, bully others, or torture animals. In some cases, acts of aggression include rape, assault with a deadly weapon, or homicide. Children with CD also may engage in destructive behavior that results in loss or damage to someone's property. For example, they may vandalize public buildings, set fires, or break up furniture in the family home. Deceitfulness – as evidenced by chronic lying, breaking promises, or stealing – is frequently evident. Finally, children with CD tend to violate important rules set by parents and school officials; for example, they may stay out late without permission or repeatedly fail to attend school without the knowledge of their parents.

Until recently, CD was thought to be rare among preschool-age children. However, studies featuring developmentally appropriate diagnostic assessment tools have shown that CD can be reliably diagnosed in 3- to 5-year-old children (Keenan et al., 2011). Moreover, Keenan et al. found that 80% of preschoolers who met criteria for ODD and 60% of those who met criteria for CD continued to receive the same diagnoses during the next 36 months. Boys were more likely than girls to follow a chronic course. Thus, it is essential to understand the types and combinations of risk factors that increase young children's vulnerability to persistent disruptive behavior problems.

Patterns of Temperament Risk

Early childhood is a time of critical development in self-regulation (Kopp, 1982). Biologically based differences in behavioral tempo and emotional reactivity may have an important impact upon the development of regulatory competence, especially if the child's interaction style leads to conflicts with caregivers and peers (e.g., Rothbart and Bates, 2006). In what follows, we describe two temperament traits that have been linked to individual differences in child externalizing behavior: regulation of attention and inhibitory behavior, and emotion reactivity and regulation, particularly proneness to anger.

Effortful control (Rothbart, 1989) refers to a general executive component of temperament that governs the child's capacity to inhibit a dominant response (e.g., grabbing a toy from a peer) and initiate a subdominant response (asking for a turn to play). The development of effortful control is governed by the maturation of the anterior attention network (Rothbart et al., 2000). Normally, developing levels of effortful control provide a foundation for adaptive socioemotional functioning, including complying with requests (Kopp, 2002), theory of mind understanding (Carlson and Moses, 2001), and normal conscience development (Kochanska et al., 1997). Conversely, toddler- and preschool-age children with deficient effortful control have shown high levels of disruptive behavior problems (e.g., Olson et al., 2005). Thus, deficits in effortful control play a key role in the development of early-onset disruptive behavior problems.

Early-onset externalizing problems also reflect deficits in multiple emotion systems (e.g., Keenan, 2000). The role of negative emotionality is particularly important. Both internalizing and externalizing problems have been linked to global constructs of early negative emotionality such as 'difficultness' or 'proneness to distress' in infancy and toddlerhood (Rothbart and Bates, 2006). However, current models of temperament and psychopathology stress the importance of differentiating distinct emotion systems as potential contributors to specific dimensions of psychopathology (e.g., Eisenberg et al., 2001). Mounting evidence suggests that proneness to frustration and anger is a specific risk factor for externalizing spectrum disorders. For example, young children who show angry responses to frustration also manifest higher levels of aggressive/disruptive peer interactions (Hughes et al., 2001) as well as generalized externalizing problems (Calkins and Dedmon, 2000).

Moreover, distinct *subtypes* of early externalizing problems may reflect contrastive patterns of abnormal emotion processes. A growing body of research suggests that some infants and toddlers at risk of persistent externalizing problems manifest abnormally *low* levels of arousal (Keenan, 2000). Studies of school-age children and adolescents have shown that high levels of 'callous, unemotional traits' such as low empathy, indifference to approval, lack of guilt, superficial affective displays are associated with serious and long-lasting conduct problems (Frick and Morris, 2004). To date, however, relatively little is known about the early developmental precursors of callous unemotional traits.

Individual differences in early regulatory competence have been correlated with distinctive patterns of neurobiological and genetic risk factors. Evidence from event-related potential studies suggests that typically developing preschool children recruit the frontal and anterior cingulate cortex when completing emotion regulation and effortful control tasks (Lewis et al., 2007). Conversely, preschool children with disruptive behavior disorders have shown less right-lateralized frontal lobe activation patterns during a resting state (Baving et al., 1999, 2000), suggesting abnormal cortical activation patterns. In addition, specific genes related to dopamine and serotonin systems have been implicated in externalizing and self-regulation problems, notably the DAT1, DRD4, and 5-HTT genes (e.g., Lavigne et al., 2013), although replication efforts have been inconsistent. Recent evidence suggests that parenting quality plays a critical moderating role in the relation between allele variants and emerging effortful control (Sheese et al., 2012; Smith et al., 2012).

Co-Occurring Developmental Influences

Early childhood is a time of rapid development in all domains of adaptive functioning. Integration across levels of children's cognitive, social, and emotional functioning is a dynamic, reorganizing process underpinned by increasing levels of cognitive maturation (e.g., Lewis, 2000). Hence, we cannot understand how early regulatory competencies contribute to children's behavioral adjustment without also considering these powerful co-occurring developmental influences. In this section, we briefly examine early developments in child social-cognitive and verbal functioning that have been linked with the development of externalizing problems.

Early Deficits in Social Cognition

Delays in social cognitive understanding have been posited to play a major role in the development of early-onset and later childhood aggression (Lemerise and Arsenio, 2000). Furthermore, early self-regulatory competence and social understanding are closely intertwined (Carlson et al., 2004). As with the development of self-regulation, children's understanding of themselves and others changes rapidly across early childhood and individual differences become quite salient (Wellman et al., 1995). One important set of competencies has been labeled 'theory of mind.' Between the ages 3 and 6, children develop an increased awareness that mental states are internal, subjective experiences distinct from behavior and contexts associated with them (Wellman et al., 2001). Examining these developments in children at risk of psychopathology is a natural and important extension of this work, providing a possible link between early mental representations and later impairments in moral understanding and conduct. For example, even after controlling for differences in verbal intelligence quotient, aggressive/disruptive toddlers and preschoolers have been found to show delays in theory of mind understanding (Hughes and Ensor, 2006; Olson et al., 2011a).

As children mature, more complex patterns of social information processing such as hostile attributional biases become important antecedents of aggressive responding (e.g., Dodge, 2006). However, there are major gaps in our knowledge of how social cognitive vulnerabilities combine with self-regulatory processes in the development of aggressive/disruptive behavior (Arsenio and Lemerise, 2004). Also, pathways between early social cognitive understanding and later *distorted* information processing are poorly understood. For example, under what conditions does delayed socioemotional understanding predispose young children to biased (hostile) social information processing in later childhood? Recent findings from our laboratory have revealed that children with relatively advanced theory of mind and emotion understanding skills at the age of 3 years tend to manifest extremely low levels of hostile attribution biases in the early school-age years (Choe et al., 2013). Thus, mature social cognitive skills in early childhood may protect children from developing dysfunctional social cognitive schemata following the transition to school.

Early Verbal Deficits

Individual differences in toddlers' cognitive/verbal maturity have been linked with their emerging abilities to regulate impulsivity (Olson et al., 2002) and strong negative affect (NICHD ECCRN, 2004). These deficits, in turn, place children at risk for conflicted interactions with caregivers and peers. Alternatively, protective social mechanisms may be 'driving' associations between early verbal skills and self-regulation. For example, Olson et al. (2002) found that toddlers who experienced enriched verbal communication with primary caregivers had more advanced cognitive and linguistic skills than others and showed superior behavioral regulation at ages 6 and 8 years. Therefore, the quality of the child's transactions with family and peers is critical to our understanding of *how* early intraindividual assets and vulnerabilities become translated into enduring patterns of social adjustment. In what follows, we outline a model for understanding the development of early regulatory competence through interpersonal transactions.

Interpersonal and Transactional Processes

Most 'difficult' toddlers and preschoolers do not manifest behavior problems in later childhood (Rothbart and Bates, 2006). The quality of the child's early relationships with family and peers is critical to our understanding of why some young children with challenging temperaments show persistent disruptive behavior, whereas others do not. As shown below, the genesis of child behavior problems reflects transactional processes linking parent–child interaction to the development of self-regulation (Sameroff, 2009).

Caregiver–Infant Synchrony

Infants' relationships with primary caregivers have been construed as 'primary learning environments' for the development of self-regulatory competence (Field, 1994). Because infants are wholly dependent upon caregivers, the quality of the caregiving environment is thought to play a critical role

in determining whether early vulnerabilities find expression in chronic self-regulation difficulties (Sroufe, 1996). Through infancy and early childhood, there is a general progression from reliance on caregivers for regulation of arousal to self-initiated modulation of affective reactions and behavioral impulses (Sameroff, 2009). Thus, sensitive caregiving, a major component of secure parent–infant attachment relationships, is thought to help the child modulate states of negative arousal, permitting positive social exchanges (Sroufe, 1996). Dysregulation, marked by the presence of dysynchronous interaction and emotional distress in one or both partners, can result from a variety of factors including insensitive caregiving (e.g., intrusiveness; overstimulation of the infant), physical disruptions in caregiving, and endogenous child characteristics such as developmental immaturity or irritable temperament (Keenan, 2000).

In prospective longitudinal studies, unresponsive mother–infant interaction has been linked to self-regulatory problems across middle childhood and adolescence (Lahey et al., 2008; Olson et al., 2000). Conversely, sensitive, responsive maternal care has been associated with the development of positive self-regulation (Feldman et al., 1999). For example, Feldman et al. (1999) measured individual differences in maternal responsiveness to microshifts in infant affect at 3 and 9 months, and found that synchronous interaction predicted self-regulatory competence at age 2, even when the effects of infant temperament and infant cognitive maturity were controlled.

Early Disciplinary Interactions

Achieving a sense of independent mastery is a major developmental challenge for toddlers. In this period of rapid cognitive, social, and motor growth, it is normal for toddlers to test parental limits and resist control. Thus, toddlerhood marks a critical transition point in the development of self-regulation (Kochanska et al., 2001). The manner in which parents and toddlers resolve these developmental challenges may forecast continuing adjustment problems. During the second year transition phase, regulatory competence is facilitated by caregiver sensitivity to the child's preferred style of engaging the social and physical environment (Bernier et al., 2010). For example, skillful caregivers may be able to channel a highly active toddler's behavior into constructive interactions. Given that, levels of child noncompliance peak between the second and third years of life, the ways in which caregivers interpret and respond to their toddlers' challenging behavior have important implications for understanding children's long-term behavioral adjustment (Olson et al., 2009)

In many previous reports, highly directive, negatively toned parent–toddler interactions have been associated with noncompliance and other early manifestations of self-control problems (e.g., Combs-Ronto et al., 2009). Early conflicts around noncompliance may place children at risk of escalating cycles of coercive interactions with parents and siblings, perhaps eventuating in later externalizing behavior. Intriguingly, however, hard-to-manage toddlers with skilled caregivers may have somewhat better adjustment outcomes than others. For example, Mesman et al. (2009) found that toddlers who were difficult to manage and had responsive, warm caregivers developed *higher than average* levels of behavioral adjustment in later childhood.

What mechanisms underlie associations between early parent–child interaction, child regulatory difficulties, and emerging behavior problems? In a longitudinal study, toddlers who showed evidence of affect dysregulation (strong defiance) with their mothers during laboratory play and forced compliance tasks were found to be at elevated risk of poor cognitive and social functioning in the early school-age years (NICHD ECCRN, 2004). Although early manifestations of emotion dysregulation were associated with multiple child, maternal, and environmental risk factors, these long-term associations held even when controlling for co-occurring early risks. Several findings offered important clues to underlying processes. First, surprisingly, toddlers in the high-risk group had not been identified by mothers as more temperamentally difficult than others in infancy. Second, the authors identified mothers who were in the lowest quartile of caregiving competence between ages 6 and 36 months; only 24% of their children were in the 'dysregulated' group. Finally, mothers in the affect dysregulation group reported feeling less close to their toddlers than others. Clearly, high-risk dyadic patterns reflect a mismatch between parent and child; predictions from child or parenting characteristics alone would be insufficient.

The nature of these social regulatory processes, in turn, may be differentially patterned in boys and girls. For example, previously we reported that low levels of effortful control were strongly associated with early-onset disruptive behavior in young preschool-age boys and girls (Olson et al., 2005). Subsequently, we have shown that poor effortful control is linked with troubled family and peer relationships in both sexes. However, significant pathways between early self-regulatory difficulties, parenting behavior, and school-age externalizing problems were found for boys only, suggesting gender-differentiated patterns of risk and promotive mechanisms (Chang et al., 2009).

In addition, a host of *contextual* factors affect the manner in which the child is perceived and responded to by other caregivers, and also may directly affect the child's ability to develop internal controls. These include factors such as parental depression (Choe et al., 2013), parental sensitivity to rejection (Callender et al., 2012), and high levels of marital discord, especially the presence of physically and emotionally aggressive responses to marital conflict (Cummings et al., 2003). Moreover, sociodemographic risks such as low parental education, poverty, community violence are powerful indicators of the amount of stress and strain on caregiving systems that predict serious long-term antisocial outcomes even before the child is born (Murray et al., 2010). Finally, as shown below, cultural factors are of paramount importance to understanding the development of early behavioral adjustment.

Cultural Foundations of Early Behavioral Adjustment

In this section, we briefly discuss how culturally shaped parental beliefs and disciplinary practices may influence the development of individual differences in young children's

self-regulatory competence, the primary foundation for behavioral adjustment. Cultural norms influence how caregivers define appropriate behavior in young children, their preferred methods of discipline, and the types of causal attributions they make when children violate social expectations, as well as the manner in which children express negative behavior (Bornstein and Lansford, 2009).

Parental beliefs about desirable child behavior reflect implicit meanings that derive in part from folk knowledge about the nature of children and their place in society. Parents' *ethnotheories* about child development have motivational properties and provide a frame of reference for interpreting and responding to child behavior (Harkness and Super, 2002). Most prior research connecting parenting beliefs with children's early behavioral adjustment has been conducted with North American samples. However, studies of countries with contrastive cultural values have strong relevance for understanding the socialization of self-regulation in young children (Tardif et al., 2009). For example, Olson et al. (2001) found that the two most salient categories of child maladjustment in Western populations, externalizing and internalizing problems, did not generalize well to the perceptions of Japanese parents of young children, whereas traits that reflected self-regulatory competence were paramount.

Similarly, Chinese parents have been shown to strongly endorse the value of promoting emotional restraint and impulse control in their children (Chen et al., 2005). Furthermore, because of a strong cultural emphasis upon maintaining social harmony, socially disruptive behavior is viewed negatively and prohibited in family and school settings (Chen et al., 2005). Thus, from young age, Chinese children are taught to suppress impulsivity, anger, and aggression (Wang et al., 2006). Conversely, cultural values concerning the importance of effortful behavior underpin Chinese parents' socialization practices around rigorous, early self-control training (Tardif et al., 2009). Practices described above predict differences in children's behavior across different cultural contexts. However, individual differences in the association between harsh discipline and child behavior *within* Chinese culture have been shown to parallel those of children growing up in the West. For example, studies have shown that Chinese parents' power assertive discipline (e.g., frequent use of prohibitions, direct commands without explanations) with their toddler-age children predicted high levels of child aggression 2 years later, whereas inductive discipline was associated with low levels of aggression (Wang et al., 2006).

Despite the importance of cultural influences on early behavioral adjustment, there has been relatively little research linking parenting and child risk factors with symptoms of externalizing behavior in non-Western preschoolers. A recent study showed that risk factors associated with disruptive behavior problems in Western preschoolers also predicted externalizing problems in children growing up in non-Western countries. Olson et al. (2011b) conducted a comparative cross-cultural study of disruptive behavior problems in preschool-age children growing up in China, Japan, and the United States. In all these three cultures, children who performed poorly on behavioral tests of impulse control and received high levels of corporal punishment showed higher levels of disruptive behavior problems than others. Thus, salient child and parental risk factors associated with the emergence of *individual differences* in disruptive behavior were similar across diverse cultural settings. Given the paucity of comparative research on this topic, these findings should be treated with caution. Much further study is needed.

Another important gap in research concerns the lack of attention given to the behavioral socialization of young children in developing countries. Recently, data from the Multiple Indicator Cluster Study (UNICEF, 2006), a nationally representative and internationally comparable household study of over 30 000 families, have revealed important similarities and differences in child socialization practices (Bornstein et al., 2012). Primary caregivers of 2- to 4-year-old children in 28 developing countries varied widely in caregiving practices known to promote children's executive skills. For example, only one-third of these caregivers read books or told stories to their young children (Bornstein and Putnick, 2012). Moreover, using data from 24 of these nations, Lansford and Deater-Deckard (2012) examined variations in disciplinary practices with 2- to 4-year-old children. Caregivers told interviewers whether they or the members of their household used disciplinary practices that included nonviolent strategies (e.g., reasoning, explaining), psychological aggression (e.g., yelling, screaming, calling the child stupid or lazy), physical violence (e.g., spanking on the bottom or extremities), and severe physical violence (hitting on the head, beating the child with an implement). Across all countries, the most frequently reported disciplinary technique was explaining to the child why certain behavior was undesirable. Use of severe violence showed the highest levels of variability across countries, ranging from 1 to 40%. National education levels were associated with lower levels of violent caregiving practices (Lansford and Deater-Deckard, 2012). Thus, educating parents about positive disciplinary strategies that promote the development of competent self-regulation is an important target for global prevention efforts.

Clinical Implications

A critical challenge for researchers is to understand the nature of the transactional processes that underlie the translation of early child vulnerabilities into stable adjustment problems. Early self-regulatory skills reflect reciprocal influences between the child and his/her social partners as well as the larger social and cultural environment (Sameroff, 2009). The fact that stable disruptive behavior problems emerge during the toddler and preschool years strongly indicates the need for early intervention. Not surprisingly, interventions focused on helping parents respond positively and effectively to provocative child behavior produces better outcomes in early childhood than interventions implemented in later childhood or adolescence (McCart et al., 2006). For example, Shelleby et al. (2012) found that a family-centered intervention (*early steps*) improved parental positive discipline and reduced behavior problems in high-risk toddlers and preschoolers. In future interventions, we may be able to directly target children's emerging effortful control and emotion regulation skills. For example, studies have shown

that we can significantly improve preschool children's executive functioning skills through repeated practice or by teaching them meta-cognitive skills (e.g., Diamond et al., 2007). Relatedly, mothers who employ frequent emotion coaching with their preschool children may protect them from developing externalizing problems when children are exposed to psychosocial risks, including exposure to traumatic stressors (Ellis and Alisic, 2013).

Summary

In summary, we have outlined a complex model of the development of early-onset disruptive behavior problems. Our core thesis is that early externalizing problems reflect failures in the normal establishment of self-regulatory competence, particularly temperament systems governing effortful control and anger regulation. Emerging research highlights the need to examine these intrachild risk markers in much greater detail, paying attention to co-occurring developments in other systems of temperament, social cognition, and communication competence. Perhaps most importantly, we must strive to understand processes underlying the *transformation* of early self-regulation problems into stable patterns of behavioral maladjustment. In our view, this requires examining complex transactions between the child, his/her caregiving system, and a broad range of contextual factors that affect the quality of the child's social experiences and learning.

Definition of the situation: History of the Concept

Rainer Egloff, Ludwik Fleck Center at Collegium Helveticum, University of Zurich and ETH Zurich, Zurich, Switzerland; and Swiss Reinsurance Company Ltd, Zurich, Switzerland

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Coined by W.I. Thomas in the early twentieth century in the context of sociological studies on education, deviance, migration and race, the 'definition of the situation' referred to the interactive social psychological process of defining reality as a basis to determine individual and group behavior, particularly in new, unfamiliar, conflictive, or crisis situations. Defining a situation also involved actualization and modification of habits – learned behavior patterns, social values, and individual attitudes. Subsequently, the concept became an integral part of social research in the classical Chicago School of Sociology and later with its inheritors, particularly in symbolic interactionism and in the microtheories of Erving Goffman. Since the Second World War, the concept had also been adopted by functionalist sociology, most importantly through Robert K. Merton who explicitly based his own concept of the self-fulfilling prophecy on Thomas' concept, forging it into a middle-range theory. Subsequently, the concept has been used and differentiated in fields as diverse as ethnography of face-to-face interaction and rational choice theory. The original attempt to generalize and model human action in an overarching and integrative way still serves to bridge the various uses.

The concept of definition of the situation refers to the interactive mental process of determining meaning and subsequently behavior by and for individuals and groups in a given situation. An individual definition of the situation refers to the way in which an individual interprets a situation so that she or he can act (Blumer, 1939: 26). The concept emphasizes the actor's perspective, which in return is shaped by social and other factors. The definition of the situation thus integrates objective and subjective factors. The definition of situation mirrors the diverse motivations and restrictions, behavior patterns and personalities, habits, crises and readjustments, whereby people make sense of their environment and their interaction with one another. The factors to be involved range from biological aspects to biographical and spontaneous experiences, they include individual attitudes, cultural values and group norms, institutional settings and authorities.

The concept has now a history of almost a hundred years in the social sciences, and particularly in sociology. The concept of the definition of the situation was developed in the context of the pragmatist movement in American social science, and it became most influential in the classical Chicago School of Sociology, providing an analytical framework for understanding human behavior in general, and particularly in grasping adjustment difficulties of individuals and groups along their life histories and regarding new environments.

After the Second World War (WWII), functionalist strands within American sociology integrated the 'definition of the situation,' and the concept of the definition of the situation became adopted in mainstream sociology, whereas proponents of microscopic social theory and qualitative research (ethnography, case study, interview, biographical research, etc.) also further developed the concept. Later, the concept was used to bridge and integrate micro- and macrotheoretical approaches. Interdisciplinary at the very outset, the concept has been widely used in sociology and in related disciplines like political science, anthropology, psychology, pedagogy, criminology, and social work. While the concept is still intensely discussed, it has also become adapted so widely, that historical indebtedness to the concept has become less obvious in many cases.

W.I. Thomas and the Situational Approach in the Chicago School of Sociology

William Isaac Thomas (1863–1947), pioneer US sociologist and founding figure of the Chicago School of Sociology, is acknowledged to first have given expression to the concept of the definition of the situation (Perinbanayagam, 1974: 521). Florian Znaniecki, who coauthored the *Polish Peasant in Europe and America* (1918–22) with Thomas, and also Dorothy Swaine Thomas, Thomas's second wife, who wrote *The Child in America* (1928) together with him, are occasionally referenced as cofounders of the concept (Wolff, 1964; Merton, 1995).

Thomas developed the concept of *definition of the situation* in the mid 1910s, in the context of immigration studies and reform pedagogy. It highlighted the interactions between individuals, groups, institutions, and cultures to understand the rationale behind human decisions, actions, and their sanctions. The concept also represents a strong statement for the cultural and social relativity of rationality, values and norms.

The concept of definition of the situation appeared in print in 1917, in a collection of *Suggestions of Modern Science Concerning Education*, which was organized and edited by Thomas. Apart from Thomas' own contribution, the volume comprised essays by behaviorist psychologist J.B. Watson, zoologist and geneticist Herbert S. Jennings, and psychiatrist Adolf Meyer. With reference to Watson's treatment of emotional reactions, Thomas opened his chapter (Thomas, 1917) by stating four wishes – fundamental interests or desires – to represent human behavior. According to Thomas, the wishes for new experience, mastery, recognition, and safety were eventually reducible to food-hunger and sex-hunger, and their expression limited by human society through the formation of a code of behavior, which itself was produced and reproduced by an interactive process Thomas called 'the definition of the

situation': "The code therefore represents the judgment of society on the activities of its members, it dictates the limits within which the desires may find expression, and it is developed by a method which we may call 'the definition of the situation'" (Thomas, 1917: 167f.). Thomas saw the defining of the situation begun by the parents, who order and forbid and inform, "… continued in the community by means of gossip, with its and praise and blame, and […] formally represented by the school, the law, the church" (Thomas, 1917: 168). Thomas emphasized the social relativity of morality and immorality, and organization and disorganization, concluding: "In short, any definition, however arbitrary, that is embodied in the habits of the people is regarded as right" (Thomas, 1917: 169).

The role of the definition of the situation to capture potential tensions between differing perceptions and value orientations was further elaborated in *The Polish Peasant in Europe and America* (Thomas and Znaniecki, 1918–21). In this classic of empirical social research the adjustment process of an immigrant group was documented, mostly through 'life history documents' such as hundreds of letters and a book-long autobiography. The study assessed the ethnic group's potential for resolution of crisis arising from migration and social change through communicative interaction and subsequent reorientation. In the 'methodological note' to the five volumes, Thomas and Znaniecki introduced a model of activity to integrate social values – socially sanctioned objects of activity – on the one hand, and individual attitudes – the individuals' tendencies or potentialities to act. The 'situation' was conceptualized as the interacting set of values and attitudes, and every concrete activity was understood as the solution of a situation (Thomas and Znaniecki, 1918: 68). While the total situation involved (1) 'the totality of values' equaled with 'objective conditions under which the individual or society has to act,' and (2) the 'preexisting attitudes of the individual or the group which at the given moment have an actual influence upon his behavior,' the 'definition of the situation' (3) represented 'the more or less clear conception of the conditions' (1) and 'consciousness of the attitudes' (2): "(…) the definition of the situation is necessary preliminary to any act of the will, for in given conditions and with a given set of attitudes an indefinite plurality of actions is possible, and one definite action can appear only if these conditions are selected, interpreted, and combined in a determined way and if a certain systematization of these attitudes is reached, so that one of them becomes predominant and subordinates the others" (Thomas and Znaniecki, 1918: 68).

The concept of definition of the situation embodied a perspective of social psychology, understood as 'the general science of the subjective side of culture', and it was to be complemented by sociology understood as "theory of social organization" (Thomas and Znaniecki, 1918: 33). While the definition of situation represented the individual and social regulation of behavior and behavior reaction, it was particularly focused at processes of adjusting an attitude, a behavioral code or a value, after former habits had been disturbed and questioned by a crisis demanding a new definition of the situation. The five volumes of the *Polish Peasant* documented migration from one cultural setting to another as representing such crises on individual and group level. Thomas and Znaniecki applied the concept of the definition of the situation to analyze how well the immigrants adjusted their behavior from the traditional norms of rural Poland to the social values of the modern American metropolis.

Throughout Thomas's subsequent work the definition of the situation remained a core concept, whether applied to studies on child development and youth deviance (Thomas, 1923; Thomas and Thomas, 1928) or in comparative ethnology of culture (Thomas, 1937). The concept reflected Thomas's interest in behavior patterns conceived of in terms of stimulus and response, of habit and crisis, in developmental directions and personalities of individuals, groups, societies and cultures. Its dialectics of subjectivism and naturalism points to the roots of the concept in pragmatist philosophy (Joas, 1993) and to a desire to make social science an objective empirical science.

Thomas had originally been a college professor for language and literature, and he was well versed in philological and hermeneutic methods (Abbott and Egloff, 2008). But with his first steps into the new field of social science in the early 1890s, he also adopted theory and research attitudes from natural sciences to study human behavior and psychologies of cultures, groups, and individuals. An admirer of William James and influenced not only by John Dewey and George Herbert Mead, but also by anthropologist Franz Boas, he gradually moved away from an early emphasis on biological factors. Race and sex as prime categories of his research were soon replaced by a preference for the individual in his biography and personality, and he developed his culturalist social psychology embodied in the concept of the definition of the situation. Thomas's 'situational approach' translated the pragmatist stances that reality is always mediated and identities achieved through social interaction into empirical social science. Some tension and ambivalence between hermeneutic foundations and scientific ambitions remained with Thomas's conceptualization, leaving it rather undecided and vague (Blumer, 1939).

Thomas exerted a dominant influence on the Chicago School of Sociology of the 1920s and 1930s, and his concept of the definition of the situation was adopted by Robert Park, Ernest Burgess, and their colleagues and students, who partly had also been students with Thomas himself. In their seminal Chicago School textbook, Park and Burgess stated that "every single act, and eventually all moral life, is dependent upon the definition of the situation" (Park and Burgess, 1921: 764). They highlighted that the plurality of 'universes of discourse' modern life was characterized by, representing diverging definitions of situation – differences in language, meanings and values individuals attach to objects and behavior. They also maintained that "common participation in common activities implies a common, definition of the situation," pointing to the assimilation of immigrants into American society, and to the role of education on the one hand, and propaganda on the other. Park and Burgess were most interested in the adjustment and change of definitions of the situation, and this was always conceived as an interactive or mutual process: "A definition of the situation precedes and limits any possible action, and a redefinition of the situation changes the character of the action. An abusive person, for example, provokes anger and possibly violence, but if we realize that the man is insane this redefinition of the situation results in totally different behavior" (Park and Burgess, 1921: 764).

Immigration studies, educational questions, and criminology remained preferred fields for the Chicago school students' use of the concept of the definition of the situation. The concept of the definition of the situation was highlighted in the educational sociology of Willard Waller, which analyzed interaction in school, and differentiated elements, modes, and closures in the process of defining the situation (Waller, 1932: 292–317). Studies on delinquency by Clifford Shaw and others were centered around case studies, often single autobiographies – 'the delinquent's own story' – providing subjective life histories and following the format from Thomas and Znaniecki's *Polish Peasant* (Shaw, 1930). Frederic M. Thrasher and others related the development of individuals and groups (e.g., youth gangs) to the structures and characters of institutions, communities, and metropolitan areas, advocating 'the study of the total situation' (Thrasher, 1928). Later, Edwin H. Sutherland's differential association theory asserted that a person 'learned' to become delinquent due to social interaction and dominant exposition to definitions favorable to violation of law (Sutherland, 1947). The classic Chicago School's emphasis on the communicative and particularly verbal aspect of the concept is exemplified in Kimball Young's essay "Language, Thought and Social Reality" (Young, 1931) – part of a *festschrift* for Thomas by former students of Thomas on the topic of social attitudes and edited by Young in 1931. Young's article underlined the function of language to convey meaning and thus "both the objective and the subjective types of anticipation" (Young, 1931: 205). The symmetric structure of autistic fantasy associations and reality was underlined by an introductory motto to the essay taken from Thomas: "If men define situations as real, they are real in their consequences" (Young, 1931: 100; Thomas and Thomas, 1928: 572).

Merton's Definition of the Situation

While Thomas's 'definition of the situation' was more a methodological standpoint than a theoretical concept and in its complexity and openness not easy to grasp, it was Robert K. Merton, in his seminal 1948 article 'The Self-Fulfilling Prophecy,' who forged it into a distinct theoretical proposition: the 'Thomas theorem.' "If men define a situation as real, it becomes real in its consequence," quoted Merton – obviously inspired by Kimball Young – from Thomas and Thomas (1928), and made it the core of his own concept of the 'self-fulfilling prophecy.' The more famous the latter became, the more Merton's take also shaped further reception of the concept of the definition of the situation itself.

Whereas the 'definition of the situation' had been an integral part of Thomas's whole approach, Merton singled it out as the centerpiece of Thomas' s work. Merton's 'Thomas theorem' captured the definition of the situation in a most comprehensive way, making it easily understood and communicated. Merton's adoption made the concept famous, but in a peculiar version. This limited and distinctly shaped version became an asset in Merton's search for middle range theory.

Merton adopted the concept in the context of his research on propaganda and mass persuasion, and the self-fulfilling prophecy (opposite to 'suicidal prophecy') came to exemplify a fundamental social problem: ethnic hostility. Formalized in relation with several other concepts, particularly in-group and out-group, Merton emphasizes the "predominant role of the in-group in defining the situation" (Merton, 1948: 208). While putting Thomas on a pedestal for his seminal contribution, Merton saw the concept mirroring a long tradition, and he identified the 'Thomas theorem' with positions set forth by Marx, Freud, and others. By equalizing it with ideology, neurosis, and paranoid behavior, Merton reduced the concept to prejudice and pathology, i.e., to a flawed perception, which confirms itself by effecting confirming behaviors (Merton, 1948, 1995: 384f.). Thomas had treated 'true' and 'false' definitions methodologically equally. Merton's programmatic reception of Thomas's concept was thus selective, implicating that the subjective definition of situation was false or systemically dysfunctional: "The self-fulfilling prophecy is, in the beginning, a *false* definition of the situation evoking a new behavior which makes the originally false conception come *true*. The specious validity of the self-fulfilling prophecy perpetuates a rein of error. For the prophet will cite the actual course of events as proof that he was right from the very beginning" (Merton, 1948: 195).

Merton understood the self-fulfilling prophecy as a basic process of society, which stabilized and reproduced power asymmetries between societal groups. While Merton's concept was explicitly anchored in Thomas's, the earlier emphasis on social *change* in the concept of the definition of the situation was moved to the background in the Mertonian approach.

Qualitative Research and Microtheory after WWII

After WWII, a revived Chicago School Tradition – with exponents like Herbert Blumer, Tamotsu Shibutani, and Anselm Strauss and theoretical programs such as symbolic interactionism – stood in opposition to structural functionalism and reemphasized the individual person and its interaction with smaller groups. Individual interpretation of perception was highlighted as a necessary ingredient to everyday behavior. The so to speak 'neoclassical' reception of the concept of the definition of the situation could not ignore the paramount impact of Merton's interpretation, but it took its chance to reintroduce, refine, and further elaborate some of Thomas's and Park's flavors. A strong interest was dedicated to the organization of change in the definition of the situation, which was analyzed as a phenomenon in time and in physical and social space. Strauss and others elaborated on professional and other reference group related organization of definitive processes. All these attempts put communicative aspects to the core of conceptualization and empirical research.

Most strongly, Erving Goffman (1922–82) emphasized the bodily aspects of the definition of situation. He investigated face-to-face interactions – social situations defined by physical copresence, and which were therefore also limited regarding extension of space and time. Goffman advocated and practiced an ethnography of communication, which researched the cultural rules of individual conduct in social situations (Goffman, 1964). Innovatively, his approach included the senses and emotions as objects of research, and the nonverbal aspects of communicative interaction were taken most seriously. Like Thomas, Goffman worked genuinely interdisciplinary and blended biological methods (ethology)

with linguistic, literature, and arts studies. His argument for the use of theatrical and dramaturgical frameworks to analyze everyday social interactions was directly tied to the concept of the definition of the situation: "A character staged in a theater is not in some ways real, nor does it have the same kind of real consequences as does the thoroughly contrived character performed by a confidence man; but the successful staging of either of these types of false figures involves use of real techniques—the same techniques by which everyday persons sustain their real social situations. Those who conduct face to face interactions on a theater's stage must meet the key requirement of real situations; they must expressively sustain a definition of the situation: but this they do in circumstances that have facilitated their developing an apt terminology for the interactional tasks that all of us share" (Goffman, 1959: 254f.). Goffman's theory sought to generalize the 'framing' of situations, and he opened his book *Frame Analysis: An Essay on the Organization of Experience* (Goffman, 1974) with a discussion of the 'Thomas theorem' insisting that people finding themselves in a situation possibly affected by a crisis would normally not create a definition but rather state what the situation was supposed to be to them. They rely on frames of interaction, reflecting social expectations and identities. Goffman identified the framing with a quasisyntactical structure, which offers stabilizing order. This evoked interpretation of Goffman's approach as rather structuralist than interactionist (Gonos, 1977). The deeper problem revealed was that the focus on instantaneous, actual situations and definitions, microscopic both in terms of space and time, had (again) gained a concentration of the definition of the situation only with limitations of the concept's reach, and with many methodological questions surfacing subsequently. In the late 1960s and in the 1970s programs similar to that of Goffman were upheld by the ethnomethodologists, who derived their theoretical foundation not from Thomas or G. H. Mead, but referred to European authors like Wittgenstein and Schütz. Scholarly feuds developed between the "ethnomethodologists" and the "dramaturgists" (McHugh, 1968; Perinbanayagam, 1974: 521). Debates and attempts also centered on operationalizations of the concept to make it more feasible for empirical research. Modes and phases of the process of defining were differentiated (Stebbins, 1967, 1969; Ball, 1972).

Experimentalization and Transdisciplinary Adaptation

In the late twentieth and early twenty-first century, the contexts of psychiatry, educational studies, psychology and interethnic studies, where the concept of the definition of the situation originated, remain important fields for its use. For its constructivist virtues, also political science and science and technology studies have adopted it. But the concept has spread much wider across the social sciences and beyond. Several factors played together to make the concept of the definition of the situation most pervasive and almost ubiquitous today. One is its original vagueness, subsequently provoking and allowing diverse and highly debated differentiations. These continuing debates gave the concept its classical status. Two other closely related factors are the concept's emphasis on the individual and the small group, and its affinity or applicability to experimental settings. Both factors allowed for direct, questionnaire-based and even scientifically measureable observation in narrowly defined settings. Experimentally induced situational crises and research on resolution was applied by ethnomethodologists and interactionists alike. The concept even made it into pharmaceutical and medical research, where it was found useful to investigate placebo effects (Glass and Barber, 1961). Two further – again closely linked – factors for the proliferation of the concept can be listed here: the integration of objectively given and subjectively perceived structures to define a situation and limit possible action, and its linkage of micro- and macrolevels of the social. These motives have found much interest for situational analysis in the disciplines concerned with decision, from philosophy to economy (Hedström et al., 1998). Conspicuously, rational choice theory has adapted the concept of the definition of the situation. In such reading, actor's rationality is scaled for the definition of the situation, and individual choice of frames provides a particular developmental path and action according to subjectively expected utility. Finally, collective intentions, decisions and actions can be aggregated (Esser, 1996). The use of the concept to bridge social micro- and macrolevels points back to its very origins.

Abstract

Degrowth calls for the abolishment of economic growth as a social objective and signifies a desired direction where societies will use less natural resources and organize to live very differently than today. This article traces the origins of degrowth from theorists of the 1970s, to the French activist movement of *décroissance* in the 2000s, to the contemporary international activist-researcher movement. We identify 10 degrowth theses concerned with the limits to – and of – growth, the relationship between growth, degrowth, and democratic politics, and the everyday and institutional alternatives that can facilitate a degrowth transition.

The Origins of Degrowth

The term '*Décroissance*' was used for the first time in 1972 by French intellectual André Gorz who responded to the Limits to Growth report by Meadows and colleagues (*see* Limits to Growth) by questioning the compatibility of zero growth or degrowth with capitalism. Gorz was inspired by Nicholas Georgescu-Roegen (1971), the intellectual pioneer of ecological economics (*see* Ecological Economics). In 1979, Jacques Grinevald and Ivo Rens edited a collection of articles by Georgescu-Roegen. The title they gave to the book was *Demain la décroissance*, translating with the prior consent of the author as *décroissance* the word 'descent' found in Georgescu-Roegen's 'Minimal Bio-economic Program' (Grinevald and Rens, 1979).

This first phase of the degrowth debate coincided with, and was reinforced by the oil crisis and economic recession in Europe, but was gradually abandoned with the advent of neoliberalism. The second phase of degrowth debates started in the late 1990s to early 2000s, this time framed as a criticism of the then dominant notion of 'sustainable development.' The center of this resurgence was France, and especially Lyon in the wake of protests for car-free cities, communal street feasts, food cooperatives, and campaigns against advertising. In 2002, the Institute for Economic and Social Studies on Sustainable Degrowth was founded in Lyon. Articles and special issues on degrowth were featured in the pages of *Casseurs de pub*, founded by ex-advertisers Bruno Clémentin and Vincent Cheynet in Lyon, *Silence*, a magazine edited by Lyon-based environmental and nonviolence activist Michel Bernard, and since 2004 *La Décroissance, le journal de la joie de vivre*, a magazine with national circulation in France, which today sells around 30 000 copies monthly. A landmark event was a 2002 conference called '*Défaire le développement, refaire le monde*,' which took place at UNESCO in Paris and included 800 participants.

Spreading from France, degrowth became a slogan mobilized by green and antiglobalization activists in Italy in 2004 (as '*Decrescita*') and Catalonia and Spain in 2006 (as '*Decreixement*' and '*Decrecimiento*'). The same year the young researcher-activist Francois Schneider undertook a year-long walking tour on a donkey to disseminate degrowth through France, receiving widespread media coverage. In 2007, Schneider founded in France the academic collective Research & Degrowth, with Fabrice Flipo and Denis Bayon, and promoted a series of international conferences, first in Paris in 2008 and then in Barcelona in 2010. The English term 'degrowth' was 'officially' used for the first time in the Paris conference, marking the birth of an international research community. As the Barcelona group from the Institute of Environmental Science and Technology (ICTA) joined the movement, the degrowth community extended beyond its initial strongholds in France and Italy. ICTA provided links to ecological economics as well as to Latin American networks of political ecology and environmental justice (see also Stonich, 2001; Environmental Justice in the United States). Following the success of the Paris and Barcelona conferences, more conferences were held in Montreal (2011), Venice (2012), and Leipzig (2014), with degrowth continuing to spread to groups and activities in Flanders, Switzerland, Finland, Poland, Greece, Germany, Portugal, Norway, Denmark, Czech Republic, Mexico, Brazil, Puerto Rico, Canada, Bulgaria, Romania, and elsewhere.

Since 2008, the English term has entered academic journals with over one hundred published articles and at least seven Special Issues in peer-reviewed journals (Kallis et al., 2010; Cattaneo et al., 2012; Saed, 2012; Kallis et al., 2012; Sekulova et al., 2013; Whitehead, 2013; Kosoy, 2013). Degrowth signifies first and foremost a critique of the growth economy. Usually, degrowth is associated with the idea that 'smaller can be beautiful.' Ecological economists have defined degrowth as an equitable downscaling of production and consumption that will reduce society's metabolism of energy and raw materials (Schneider et al., 2010). But our emphasis here is on different, not only less. Degrowth signifies a society with a smaller social metabolism but more importantly, a society with a metabolism that has a different structure and serves new functions. Degrowth does not call for doing 'less of the same.' It calls for doing things differently. To use a metaphor: the point is not how to make an elephant leaner, but how to turn an elephant into a snail.

Degrowth should not be confused with negative gross domestic product (GDP) growth. Still, a reduction of GDP, as currently counted, is a likely outcome of actions promoted in

 http://dx.doi.org/10.1016/B978-0-08-097086-8.91041-9

the name of degrowth. A green, caring, and communal economy will be ecologically and socially sustainable, but unlikely to increase GDP by 2–3% each year. A key question then becomes how to make the inevitable decrease of GDP socially sustainable, given the dependence of the current system on growth (Jackson, 2009).

In the minds of the majority of the population, growth is still associated with improvement or well-being. For degrowth advocates, the purpose of using a negation for a positive project is precisely to decolonize an imaginary dominated by a one-way future consisting only of growth. It is the automatic association of growth with 'better' that the word degrowth wants to dismantle (Latouche, 2009).

In what follows, we identify 10 main theses emerging from the degrowth and associated literatures. We divide these into three broad categories, each corresponding to a different intellectual strand: the first with ecological-economic thought emphasizing the limits to – and of – growth; the second with cultural critiques of heteronomy and liberal democracy mainly from anthropologists and political philosophers; and the third with the search for alternatives, in which the degrowth literature meets the social-science literature on post-capitalist politics.

The Ecological-Economic Strand

Thesis 1: Growth Is Senseless

Skidelsky and Skidelsky (2012) argue that the pursuit of endless growth is senseless, since money can only be a means to an end, not an end in and for itself. If the end of a society is the 'good life,' then at some point a society should produce enough wealth to achieve it, making further growth unnecessary. Developed economies have accumulated wealth unimaginable a few generations back, yet they seem compelled to keep growing. A key question the degrowth literature addresses is why is it so.

At the micro-level of individuals, insatiability is driven by the competition for positional goods. Once basic material needs are satisfied, extra incomes are devoted increasingly to positional goods (e.g., a house bigger than the neighbor's). Relative, and not absolute, wealth is what matters. The growth of an economy, however, does not change relative positions. Yet, growth and productivity gains in the material sector increase the price of positional goods. Growth therefore makes positional goods socially scarcer. These are the social limits of growth, that is, intrinsic limits regarding the ability of growth to satisfy well-being (Hirsch, 1976). Such limits are one reason why above a certain level, growth does not increase average happiness (for a review of this literature see chapter on 'Happiness' in D'Alisa et al., 2014).

From an individual perspective it makes sense to pursue more wealth to climb up the positional ladder, but collectively this is a zero-sum game. Aggregate growth is the result of this senseless positional competition between individuals that makes no one better. The promise of growth, on the other hand, is the only way in which the illusion of upward social mobility can be temporarily sustained in the absence of redistribution. Either way, the end result is a senseless pursuit of growth for growth's sake (see chapter on 'Social limits to growth' in D'Alisa et al., 2014).

Thesis 2: Growth Is Uneconomic and Unjust

Growth no longer increases collective welfare. This failure cannot be captured by GDP, because GDP measures growth and not welfare. It does not distinguish welfare-improving from welfare-decreasing economic activity. For example, expenditures to clean an oil spill, build prisons, or wage wars increase the GDP. Independent measurements of well-being, such as self-reported life satisfaction and other happiness indices, or alternative welfare indicators such as the Genuine Progress Index or the Index of Sustainable Economic Welfare, confirm the hypothesis that above a certain level, growth does not improve welfare (Dietz and O'Neill, 2013).

The social costs of growth include bad psychological health, long working hours, congestion, and pollution (Mishan, 1967). The commodification and introduction into the formal GDP economy of ecosystem services and unpaid activities (D'Alisa and Cattaneo, 2013), or the monetization of social relationships such as hospitality or care are eroding sociability, community, and the environment. They also underline moral norms that used to regulate better such social and environmental relations (Hirsch, 1976). This might explain why the relationship between growth and a range of social indicators such as education or safety from crime is gamma-shaped: for low levels of GDP the wealthier a country is, the better its social conditions, but for high levels of GDP, more growth does not make a difference. Some argue that growth is achieved because of increasing costs rather than by a rise in benefits. In other words, growth has become uneconomic (Daly, 1996). Instead, there is a clear correlation between equality and social well-being (Wilkinson and Pickett, 2009).

The continuous growth in the social metabolism of the global economy is also causing social and environmental havoc in the commodity frontiers where energy and raw materials are extracted from, and waste disposed to (*see* Ecological Economics). Growth is sustained by an unequal exchange of resources and materials. This raises questions of environmental justice (*see* Environmental Justice in the United States): the material benefits of extraction and consumption accrue in wealthy areas or among better-off groups (elites) while the costs are shouldered by socially marginalized communities and neighborhoods. The uneven nature of development is a basic insight from political ecology (Stonich, 2001). The implication is that although growth is uneconomic as a whole, it can as well be sustained as long as the benefits accrue to the elites that hold power and the costs shifted elsewhere.

Thesis 3: Growth Is Ecologically Unsustainable

There are strong linkages between the scale of an economy and environmental impacts, from ecosystem loss to greenhouse gas emissions. Some posit the possibility of dematerialization, meaning the decoupling of raw material use and carbon emissions from economic growth. There is no evidence of such dematerialization taking place globally, and where it does it is nowhere near the necessary pace to avoid resource exhaustion or disastrous climate change. Some wealthy economies show signs of slow dematerialization for selected materials or energy sources, but this can also be the

artifact of substituting domestic production with imports from industrializing countries (see chapter on 'Dematerialization' in D'Alisa et al., 2014).

One reason dematerialization is very difficult is because the more efficient an economy becomes, the more resources it might consume (see chapter on 'Jevons' paradox' in D'Alisa et al., 2014). Technological advancements lead to a more efficient use of resources, reducing their cost, but raising the demand for them, making new uses more affordable.

The prospect also of a structural transition to 'weightless,' service-based information economies is unlikely. The emergy (embodied energy) of services is much higher than that of primary activities. Service activities are ecologically subsidized by commodity extraction and industrial production elsewhere (Odum and Odum, 2001).

Thesis 4: Growth Is Coming to an End

While growth beyond a certain threshold does not deliver social or environmental benefits, it also gets harder and harder to sustain over time. There is evidence of a declining long-term rate of growth in developed economies (Gordon, 2012). Some have attributed this to diminishing marginal returns (Bonaiuti, 2014), while others to the exhaustion of major technological innovations, such as the oil-fuelled combustion engine and associated changes (cars, highways, suburbs) that propelled accumulation in the twentieth century (Gordon, 2012). Yet others point to limits in creating effective demand and finding constantly new investment outlets for capital accumulating at the compound rate of 2–3% growth per year (Harvey, 2010).

Degrowthers instead are likely to postulate ecological limitations. A main argument from the bioeconomics of Georgescu-Roegen is that economic growth accelerates entropy. Economic growth degrades high-order (low entropy) stocks and turns them into low-order (high entropy) heat and emissions. Energy cannot be recycled, and materials can be recycled only to some extent. Since the earth has a limited amount of exhaustible stocks (such as raw materials and fossil fuels), in the long run economic activity can only be sustained at the rate of the flow of solar energy (Georgescu-Roegen, 1971).

How long into the future existing energy and material stocks can last is subject to considerable debate. Some treat peak oil (and other peaks in the extraction rates of essential raw materials such as phosphorous) as evidence that stock exhaustion is already limiting growth (*see* Mineral Resources, Limits to: The Case of Peak Oil). Others point to different estimates, or to opportunities for substitution, e.g., of oil by gas or coal. Climate change, a manifestation of what Georgescu-Roegen called 'thermal pollution' from increasing entropy, may restrict economic activity before resource exhaustion does. This will depend on the pace of transition to cleaner sources of energy. Bioeconomists are skeptical of such a transition because they calculate that renewable sources produce much lower energy surpluses (energy returns to energy investment, EROI) than conventional sources (Murphy and Hall, 2010). This means that much conventional energy will need to be expended in the transition to renewables. It also means that the scale of a 'solar economy' will have to be much smaller than the current one, given the actual lower EROI of renewable energies compared to fossil fuels.

Degrowth scholars who analyze the current crisis have postulated that resources have already limited the growth rate of the real economy. Such limits were temporarily superseded with the rise of the fictitious (bubble) economy of finance, which sustained growth for a little while more. In other words, an otherwise unsustainable rate of growth has been sustained through private and public debt (Kallis et al., 2009).

The Culturalist Strand

Thesis 5: The Growth Consensus Has Eroded the Political

Political philosophers have criticized the increasing depoliticization of public debate in Westernized democracies. Some have attributed this trend to the rise of neoliberalism and the 'Washington consensus' that subjugated sovereign political choice to the needs of unregulated capital and liberalized markets. Degrowth scholars agree with this explanation, but trace the origins of depoliticization further back in time and into the imaginaries of development and growth that became hegemonic after the Second World War (see chapter on 'Critiques to Development' in D'Alisa et al., 2014). Since its inception, the notion of economic development was tightly linked to that of growth, referring to the replication in 'underdeveloped areas' of the conditions characterizing industrialized nations, such as specialization, production for markets, agricultural intensification, urbanization, and modern values.

The discourse of 'sustainable development' (*see* Sustainable Development), degrowthers claim, has had a depoliticizing effect too, decoupling environmentalism from its radical critique of modernity and its aspirations to challenge dominant notions of the good life. Degrowth was thrown explicitly as a 'missile word' to *re-politicize* environmentalism and challenge the consensus around sustainable development (Fournier, 2008). With its emphasis on win–win solutions and the utopian goal of perpetuating development without harming the environment, degrowthers charged, sustainable development depoliticizes genuine political antagonisms about the kind of future people want. It evades the core question, which in Bruno Latour's (1998) terms is whether 'to modernize or ecologize.' Ecologizing society, degrowthers argue, is not about implementing an alternative form of development. It is about imagining and enacting alternatives *to* development (see chapter on 'Critiques to Development' in D'Alisa et al., 2014).

Some degrowth advocates trace depoliticization further back than neoliberalism or the post-war ideology of development, focusing instead on the origins of modernity (see chapter on 'Dépense' in D'Alisa et al., 2014). According to the theory of *dépense*, societies always have an excess (surplus) of resources over what is necessary for the mere reproduction of life: politics is about the collective choice of the destination of that surplus. The main innovation of capitalism was the (institutionalized) investment of a significant part of the surplus into new production. This allowed for the growth take-off during the eighteenth century. Consequently, capitalism has disavowed the exercise of political sovereignty *par excellence*, namely collective decisions for the destination of surplus. Older civilizations, for example, defined their purpose through different forms of unproductive surplus expenditure, with members

creating meaning by building a pyramid, supporting a class of monks, or idly philosophizing. This collective pursuit of sense has been lost in capitalist civilization, having been relegated to the individual sphere. Acts of *dépense* have been commodified and individualized. Indeed, the promise of modernity is that the meaning of life is to be found by each individual alone, and that in this pursuit he/she has every right to mobilize all the resources necessary. At the societal level, this translates into the non-negotiable demand for growth. As individuals search for meaning, the genuinely 'political' sphere where meaning is to be collectively constructed has been subordinated to the imperative of growth (see chapter 'From austerity to Dépense' in D'Alisa et al., 2014).

Thesis 6: Limits Liberate

Degrowth thinking in the 1970s associated with names such as Andre Gorz, Ivan Illich, and Cornelius Castoriadis has framed limits not as externally imposed but as a conscious choice that is part of a collective political project. Limits in this vein are 'a social choice and not imposed as an external imperative' (Schneider et al., 2010: 513). This argument for self-limitation in the face of environmental degradation is neither an intrinsic one ('let's save nature for nature's sake') nor a utilitarian one ('let's save nature to save ourselves who depend on it'). It is an argument for a simpler life in more harmony with the nonhuman world, a life that for degrowthers is the one that is worth to be lived.

Ivan Illich (1973) proposes that simplification and self-limitation, which he calls conviviality, is necessary for autonomy, and by extension for genuine democracy and equality. Convivial tools and spaces are those which are understandable, manageable, and controllable by their users. A house built and repaired by its users is convivial; a 'smart' building whose temperature is controlled by software is not. Autonomy means that people are in control of their tools and spaces, meaning that these are not produced or governed somewhere else. Illich took issue with fossil fuels not because of peak oil or climate change. His problem was that high energy use supports complex technological systems that cannot be directly controlled by their users. Such systems by their very nature call for specialized experts to manage them. This division between experts and nonexperts inevitably creates inegalitarian hierarchies and concentrates power. Equality and democracy are unlikely as long as people do not have sovereign and shared control over their means of subsistence and production. From this perspective, degrowth is antithetical to ecological modernization and ecoefficient technologies, such as large-scale renewable projects (industrial wind farms or the Sahara–Europe solar panel project) or high-speed trains, not only because these might be insufficient or not green enough (Thesis 3), but because of their non-convivial complexity.

André Gorz (1982) developed a somewhat similar argument, but with the concept of autonomy he emphasized freedom from wage labor. Gorz defined as autonomous the sphere of nonpaid work where individuals and collectives enjoy leisure or produce for own use, rather than for commodified exchange. The sphere of reproduction and care belongs to the autonomous sphere. Unlike Illich, Gorz was not critical of industry; he envisioned a dual industrial-autonomous society, consisting of an economic sphere where industrial goods and services are produced with the maximum possible efficiency, thereby liberating more and more time to be spent in the autonomous sphere. He also advocated for decentralized micro-industries using a 'digital fabricator' (similar to a 3D printer), similar to contemporary projects such as Open Source Ecology where innovation depends upon open collaboration. Gorz criticized the socialist dream of a collective and democratic control of the means of production; modern production lines are too complex to be controlled by workers without delegates, he argued. Industries should be governed by democratically controlled States and secure the basic material needs of everyone. Socialism will only come through liberation from wage labor, not by a change of wage labor conditions. Despite a slightly different logic from Illich, Gorz therefore also advocated for the expansion of an autonomous sphere of low-intensity, decommodified, frugal activities.

It is in this vein that more recently Serge Latouche (2011) argued that abundance can be found in frugality. For him abundance is a matter of relational, not material goods. It is a matter of autonomy and conviviality. Only a society that decides 'it has had enough' and limits itself from pursuing what can be pursued can solve the problem of scarcity, satisfying itself within what is available. Only a society that is egalitarian and shares what is available can break away from the positional inequalities that sustain insatiability and construct a sense of generalized scarcity.

In this spirit, some degrowthers emphasize that they find inspiration for their theory, not in Malthus but in the Neo-Malthusians anarcho-feminists of Emma Goldman, who advocated conscious procreation in their fight against capitalism and the exploitation of female bodies to produce soldiers and cheap labor (see chapter on 'Neomalthusians' in D'Alisa et al., 2014).

The 'Alternatives' Strand

Thesis 7: A Transition beyond Growth Is a Transition beyond Capitalism

Capitalism here is understood as an ensemble of institutions – private property, the corporation, wage labor, and private credit and money at an interest rate – whose end result is a dynamic of profit in search of more profit ('accumulation'). Degrowth, even in a narrow sense of downscaling the material throughput of an economy, is unlikely to be compatible with capitalism if growth cannot be decoupled from throughput. This is the case even if *in theory*, as some steady-state scholars argue, a universal and declining cap on material and energy throughput could force capitalist economies to work within limits (Lawn, 2011). In practice, however, lack of growth increases workforce exploitation to maintain or increase the rate of profit (Blauwhof, 2012; Harvey, 2011). This in turn renders capitalism and liberal democracy socially and politically unstable under conditions of lack of growth. Growth avoids redistributive conflict and sustains capitalism politically. It is in this concrete sense that growth is necessary for capitalism.

Lawn (2011) advocates a scenario where collective limits (caps) are set, and then social security policies (such as a Job Gurantee to all by the State) are applied to ensure that

downscaling does not threaten the basic well-being of anyone. However, as Blauwhof (2012) argues radical political changes would be necessary to allow such seemingly innocuous policy 'reforms.' In existing capitalist democracies there is inequality in political power, distributed roughly along the lines of economic power. Caps, taxes, or redistributive income/job security programs are likely to harm economically powerful interests with privileged access to governments. A radical rearrangement of power relations would be necessary if these were to be enacted, and after those, capital would not anymore act as the predominant social force.

Thesis 8: Degrowth Alternatives Already Exist

Degrowth has also served as a structuring concept for connecting a diversity of post-capitalist, low-carbon alternatives. In the literature there is an engagement with alternative institutions at both the micro-level of community organization and the macro-level of State economic regulation.

For example, as alternative to the primacy of the institution of private property under capitalism, degrowthers emphasize the reclaiming of – and the making of new – commons, with access to goods and services based on sharing. Illustrations of this are ecocommunities and co-housing projects experimenting with forms of nonprivate housing where users share common space and invest their own labor in the making and maintenance of their shelter. Other examples of new forms of property are pirate programmers and on-line communities of digital commons who break away from private intellectual property, making new 'copy-left,' open digital products (Carlsson, 2008). Cooperatives of workers and users challenge the corporate form of privatized ownership of the means of production and break away from rents and profits. In the field of food production, and unlike corporate agri-businesses, agroecological farmers and back-to-the-landers produce for subsistence and for alternative food networks linked directly to consumer cooperatives without passing through intermediaries. In urban gardens accessed and preserved in common, city dwellers produce their own food and conserve their own recreation spaces, putting nonpaid work into their subsistence and leisure. Degrowthers, in the tradition of Illich, are also concerned with and contribute to various new institutions of education or care, such as parental-cooperative daycare and schools, where parents participate directly in the education of their children.

Such nowtopias (Carlsson, 2008) share five features: first, a shift from production for exchange to production for use (by participants or end-users); second, a partial substitution of wage labor with voluntary participant activity, meaning a decommodification and de-specialization of labor; third, an anti-utilitarian logic, where circulation of goods is set in motion, at least partly, by an exchange of reciprocal 'gifts' rather than the search for profit; fourth, an intrinsic value assigned to connections ('commoning') and relations in and for themselves; and fifth, the lack of a built-in dynamic to accumulate and expand (D'Alisa et al., 2014).

From a sustainability perspective, what is interesting is the relative low-carbon/material content of many such alternatives compared to conventional State or market systems that provide the same services (D'Alisa and Cattaneo, 2013). In some cases, such as, for example, food production, alternative systems may be less efficient than conventional systems per unit of product, given the lower degree of specialization and the limited division of labor (though this would probably be less so if one were to also account for the environmental costs of inputs such as oil). Even so, such alternatives are likely to be more environmentally benign precisely because their unproductiveness limits their scale (a "debound", or inverse rebound or Jevons' effect).

There is an interesting proliferation of new communal institutions and forms of production under conditions of economic crisis, as evidence from Argentina, Catalonia, or Greece suggests. The insight here is that as the conventional institutions of capitalism fail to cater for the basic needs of people, there is a spontaneous rise of new institutions concentrated in the autonomous sphere (Conill et al., 2012). Such institutions do not have to substitute State functions (of care, education, social security, or provision of basic goods). Instead they can offer alternatives that transform the functions of the States without dismantling them, challenging in this way the tendency toward privatization of State assets and services.

At the level of government policies, the degrowth literature has investigated labor and social security institutions that can secure meaningful employment in the absence of growth, supporting where possible the expansion of the autonomous sphere. A job guarantee scheme proposes to make the State an employer of last resort, reducing *de facto* unemployment to 0 and subsidizing care or autonomous activities through State expenditures (see chapter on 'Job Guarantee' in D'Alisa et al., 2014). An unconditional basic income to all citizens, eventually coupled with a ceiling income and financed by progressive taxation on wages and profits, can secure a basic level of subsistence and security for all without access to wage labor. With basic needs covered, the proposition is that there will be more opportunities to dedicate one's time in the autonomous sphere and perhaps share work through part-time employment in the paid sector (see chapter on 'Basic and Ceiling Income' in D'Alisa et al., 2014). Worksharing, achieved through a redistribution of work between the employed and the unemployed via a reduction of working hours in the paid sector, can also reduce unemployment, and redistribute wealth if implemented with income parity (Kallis et al., 2013). The concern addressed by these three institutions is that if technology and productivity keep improving, a lack of growth will render redundant a growing part of the workforce. The State can then redistribute some of the benefits of increased productivity to subsidize liberated time and the autonomous sphere.

Another degrowth strategy for solving the unemployment problem is a State-supported structural shift to a New Economy of social and cooperative enterprises focusing on services (care, health, education, leisure). Such activities have low productivity but are more labor-intensive and provide meaningful employment. Although they have low economic value, they have high social value and can form the basis of a degrowth economy (Jackson, 2009).

Regarding money and the credit system, institutional proposals emerging from the degrowth literature include zero interest rates (Loehr, 2012) and very high reserve requirements for banks to limit credit bubbles that drive fictitious material growth (Daly, 1996). Community currencies, time banks, and barter exchanges have the potential to relocalize economic activity, control its scale, and break away from the

expansionary dynamics of the monetary system. That said, experiences with community currencies suggest that they can at best serve as small-scale complements to mainstream currencies. State money will continue to be a more important locus of change given the need for interlocal exchange in a complex economy, the fact that taxes (a large part of gross economic product) are paid in conventional money, and the vast amounts of financial and organizational resources required for stable large-scale monetary systems.

A related degrowth proposal is for the State to take back control of the money supply from private banks (see chapter on 'Public money' in D'Alisa et al., 2014). Money issued as debt creates a growth dynamic. Currently, money is mostly created through private banks. While private banks can only issue money as debt through loans, the State could also issue money free of debt to meet public needs, for example, by financing a basic income or a job guarantee scheme or by subsidizing cooperatives, care services, or renewable energy projects. By providing money themselves, states would also reclaim seigniorage (the difference between the nominal value of money and the cost of producing it), and save money by not having to pay private banks for borrowing to finance public expenditure.

Concerning debt, degrowthers have argued that the economy cannot be expected to grow at the rate necessary to pay fictitious debts (Kallis et al., 2009). Debt is a social relation, and history is full of examples of societies that forgave debts and started afresh. Western societies have maintained a materially affluent life-style by shifting promises of payment to the future. Debt forgiveness might trigger a decline in the living standards of small creditors and savers. From a degrowth perspective, the goal cannot be to relaunch growth to repay debts but to distribute fairly the costs of such an adjustment. It is legitimate to excuse the debts of those whose basic standard of living is threatened, and not pay those who lent for profit. Some credits are more legitimate than others. The assessment and decision should be democratic. In this vein, degrowthers advocate citizen-run Debt Audits.

Thesis 9: The Politics of a Degrowth Transition Are Open and Plural

How all those alternative property, work and credit, micro and macro institutions could be connected in an alternative form of social and political organization remains subject to considerable debate. There is also no agreement concerning the political strategies needed to replace the current institutions of capitalism with alternatives. Latouche (2009) sees change coming through parliamentary politics, positing degrowth as a program for parties of the Left, though not with a party of its own. Others see a more spontaneous networking and flourishing of post-capitalist alternatives occupying more and more political and economic space as the old system of States and corporations collapses. From this perspective, alternative practices of education, food provision, living, and producing (see Section Thesis 8: Degrowth Alternatives Already Exist) are 'political' practices: they challenge and develop concrete alternatives to the dominant institutions of capitalism. From a Gramscian perspective, everyday practices that rearticulate the common senses of the civil society are as necessary as the struggle for leading the political institutions in *strictu sensu*.

For some degrowthers, a transformation of the political system into a more assemblarian and direct form of democracy is part and parcel of a degrowth transition. They find hope in social movements such as the Indignados (Occupy), whose politics prefigured values and projects similar to those of degrowth. In general, in degrowth debates there is openness to a plurality of possible degrowth strategies and political subjects, ranging from nonwage labor nowtopians with a shared experience of living and producing in the autonomous sphere, to existing social movements, political parties, and Unions. D'Alisa et al. (2013) break down degrowth into civil and 'uncivil' strategies and actors, with the latter being defined as those who refuse to be 'governmentalized.' Organized disobedience features in the repertoire of degrowth activists, spanning from the occupation of abandoned houses ('squats') to sit-ins against megaprojects and coal plants, or financial disobedience such as that of Enric Duran, a prominent advocate of degrowth in Barcelona who 'expropriated,' in his own words, 492 000 Euros via loans from 39 banks in 2008, in order to both denounce the predatory credit system and dedicate that money to social projects (D'Alisa et al., 2013).

Thesis 10: Degrowth in the North Will Let the South Live Well

Degrowth in the Global North is advocated in order to liberate ecological space for improvement of living conditions in the South. This runs against the standard proglobalization argument that growth in the North is necessary so that the South has growing markets to export its products. Degrowthers would point to the historical fact that the Global North did not need growing markets in the South in order to grow, but rather cheap natural and human resources which it exploited. In fact, one could argue that degrowth in the North today will reduce demand for natural resources and industrial goods, making them more affordable and accessible to the South.

Even so, this economistic formulation of North–South relations is unsatisfactory from a degrowth perspective, as it leaves the imaginaries of growth and development intact. The intellectual roots of degrowth can be traced to the post-development literature and the criticism of the imaginary of development for the 'Third world.' The proposition here is that the rejection of growth in the North therefore can also stop the colonization of imaginaries in the South, increasingly streamlined in a one-way future consisting only of growth. There is actually no lack of alternative imaginations about the good life in the South. Examples include Buen Vivir in Latin America (or Sumak Kawsay in Ecuador); Ubuntu in South Africa; or the Gandhian Economy of Permanence in India (D'Alisa et al., 2014). Such visions express alternatives *to* development, alternative trajectories of socioeconomic organization. The degrowth proposition is that these stand to flourish by a retreat of the growth imaginary in the Northern countries that have promoted it, if not forced it to the rest of the world.

The Future of Degrowth

Research-wise, there is much to be done in modifying and challenging each of the 10 theses, producing new ones and further diversifying the field (Kallis et al., 2012). More research,

for example, is necessary to demonstrate that growth is ecologically unsustainable, or that dematerialization is impossible and insufficient. More historic data is necessary to support the thesis that we are facing systemic, and not a periodic, stagnation and that resource limits have something to do with it. The claim also that the abandonment of growth may revive political debate and nourish democracy, rather than animate catastrophic passions, is for the time being speculative. In general, such claims are firmly established *within* the degrowth community, but they are far from being accepted in wider society where dematerialization and green growth continue to be seen not only as possible, but also likely.

More research is also necessary to understand how and why people and nations adapt to the lack of growth, why some alternative institutions succeed and challenge capitalism while others collapse or get incorporated into the mainstream, or how, and under what conditions, institutions such as work-sharing or a basic and ceiling income will work and produce the outcomes their advocates claim they can produce.

Another question concerns the social dynamic, the actors, the alliances, and the processes that will create a degrowth transition. This question is not just intellectual and cannot be answered only by research. Social change is a process of creation and is impossible to predict in advance. What academic studies of degrowth can offer are new narratives to animate the politics of a transition. Degrowth research is not only inter- and transdiscpilinary. It is transparent about its values and politics, and is based explicitly on a model of post-normal science, researchers, practioners, and activists collaborating in novel formats, as, for example, the working groups of the international degrowth conferences (see Cattaneo et al., 2012). The 10 theses presented here are outcomes of this process and already animate politics. But if the degrowth debate is to keep its momentum, there is no reason to be restrained to those.

Dehumanization

Chiara Volpato, University of Milano-Bicocca, Milan, Italy
Luca Andrighetto, University of Genova, Genova, Italy

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Dehumanization is the act of denying humanness to other human beings. Throughout history, dehumanization has been an essential ingredient in the perpetration of intergroup violence and atrocities. The first section of this article defines the phenomenon and describes its different manifestations. Theoretical and empirical works on blatant dehumanization are then reviewed. In the third section, the functions fulfilled by dehumanization for groups and individuals are summarized. The fourth section presents more subtle and unconscious forms of dehumanization. In particular, the concept of infrahumanization is introduced with a summary of empirical evidence. The fifth section focuses on phenomena of objectification and self-objectification, and reviews work from the formulation of objectification theory until the most recent studies. Finally, new directions for investigating unexplored aspects of this phenomenon are proposed.

The Course of Dehumanization

Dehumanization involves denying humanness to others, introducing an asymmetry between people who have human qualities and people who are perceived as lacking these qualities. Dehumanization is a radical form of out-group derogation intrinsically linked with conflicts and mass killings. According to Tajfel (1981), the dehumanizing processes stem from intergroup contexts in which group members have undifferentiated perceptions and behaviors toward out-group members; such uniformity leads to depersonalization (in social psychology, depersonalization refers to the stereotypical perception of the self as an example of some defining social groups), which is the prelude to dehumanization. Dehumanization is many sided, multifaced, and flexible. It fits in places, people, and relations, and from time to time, it assumes the forms required by the social context and the *Zeitgeist*. The forms of dehumanization are various: subhuman, superhuman, objectifying, biological, and mechanical metaphors have developed over time. They are described below.

Animalization

Animalistic dehumanization reduces the target to subhuman levels, by denying the qualities that define human primacy over other living beings. Individuals perceived as lacking these characteristics are judged as irrational, immature, coarse, unlearned, or lacking self-control. Furthermore, they are accused of having impulsive behaviors, and of being driven by primitive impulses. People who are dehumanized in the animalistic manner feel degradation and humiliation; those who dehumanize feel disgust and contempt toward the dehumanized targets.

Throughout history, the animalistic metaphor, more than other dehumanizing metaphors, has been used to derogate the out-group to an inferior level. The animal has always been an important comparative example in the definition of human identity. Human beings indeed define themselves through their supremacy over animals, even if, at the same time, they use animals for justifying their supremacy over other human beings. Social groups excluded from 'full humanness' are subjected to treatments, which vary according to how dangerous they are considered. They may be likened to domestic animals, and thus they become targets of paternalism and exploitation, or they may be likened to wild beasts, in which case they suffer contempt, repressions, and mass killings.

Animalization is tightly linked with the Western culture; think about the barbarian definition coined by the classical world, or about the definition of native populations used during the conquest of the New World. European intellectuals discussed at length these definitions and wondered whether these individuals were humans, 'homuncoli,' or even apes. Animalistic dehumanization has been used for sanctioning white supremacy in colonial contexts, for portraying enemies as criminals during intergroup conflicts, and for delegitimizing women and lower classes within nations (Jahoda, 1999).

To date, psychosocial research has primarily focused on the negative side of animalistic dehumanization. In contrast, the positive valence of many animal metaphors has received little attention. In fact, animals have often represented power and high status. For instance, the emblems of many kingdoms portray images of lions, eagles, or griffins. Furthermore, philosophers and literary men refer to animals when talking about humanity and its problems; think about works by Esopo, Fedro, La Fontaine, Melville, Carroll, Collodi, and Orwell, or Dante and Machiavelli's allegories. Thus, the use of animal metaphors is more complex than what psychosocial research has documented, and requires a more articulated investigation that involves both positive and negative meanings.

Demonization

Demonization is a suprahuman metaphor that transforms other people into demons, devils, or witches. Through demonization other people are attributed supernatural powers with the aim of exacerbating their dangerousness, and thus legitimizing their elimination. Such representations stem from the classic concept of *monstrum* (i.e., monster): the one who *monstrat*, that is the one who 'shows.' The *monstrum* indeed shows a gap in the 'natural' norms ruling the relationships

between human beings and animal species. This gap may take the form of excess, defect, or malformation. Within the classical world, the monster was not necessarily considered as a negative character. For instance, the giants were symbols of greatness, rather than dangerousness. However, during Christianity the monster was replaced by the devil, which became the essence of evil (Le Bras-Chopard, 2000). Demonization is still used in the world today, as shown by recent events of 'witch-hunting' in some Central African countries, or by the imprisonment of political opponents accused of using magic in Iran. Notwithstanding the persistence of demonization, psychosocial studies have dedicated little attention to this metaphor.

Biologization

Biological metaphors are rooted in sixteenth-century Spain with the cult of the *limpieza de sangre*. However, they mostly developed during the nineteenth century, concurrently with the rise of scientific racism and social Darwinism.

Biologization employs metaphors linked to illness, hygiene, or purity; biologization involves transforming others with microbes, viruses, pestilence, cancer, dirt, and pollution (Douglas, 2002). Since Enlightenment, germ theory replaced the demon as metaphor of a dark danger. Individuals who were dehumanized in the biological manner had to face drastic measures, similar to those enacted to defeat emergencies and epidemic diseases. In other words, they must be defeated through practices of cleanliness, elimination, disinfection, extirpation, or purification. Most leaders guilty of twentieth-century genocides have been inspired by these practices.

Mechanization

Mechanization is a creature of the modern times. This is a dehumanizing metaphor that is gaining ground in the world today. Mechanization involves perceiving others as mechanical organisms, that is, robots that are incapable of feeling emotions and disclosing to others. Individuals who are denied such characteristics are judged as indifferent, cold, rigid, passive, lacking in curiosity, imagination, and depth; they are perceived as machines; and they do not elicit tender feelings, compassion, or empathy. The most meaningful examples of mechanistic dehumanization may be observed in medical and technological domains, that is, within those contexts in which the standardization of procedures, the myth of efficiency, depersonalization, and forced passivity wear away the richness of interpersonal interactions (Haslam, 2006). The mechanistic metaphor has been most applied in the industrial world, where Taylorism theorized the parceling out of mass production and the subordination of workers. Taylor's ideal was a worker without mental capacities and intellectual autonomy, a worker only capable of carrying out standardized actions: an estranged living being, a programmed robot.

Objectification

When objectified, individuals are perceived as objects, instruments, or goods. The objectification process leads to "a kind of instrumental fragmentation in social perception, the splitting of a whole person into parts that serve specific goals and functions for the observer" (Gruenfeld et al., 2008: p. 111). Objectification is embodied in the figure of the slave. Regrettably, this figure is still present in the world today: a new form of slavery – known as debt bondage – has indeed replaced the old slavery.

The concept of objectification was first introduced by Immanuel Kant. In *Metaphysics of Morals*, he argued that objectification refers to the perception of others as mere sexual instruments. During the past years, this concept has been widely analyzed by feminist thinking, which has focused on the sexual objectification of women (Papadaki, 2007). According to this perspective, objectification implies the perception and evaluation of a woman only on the basis of her sexual parts or functions, which "are separated out from her person, reduced to status of mere instruments, or else regarded as if they were capable of representing her. To be dealt with in this way is to have one's entire being identified with the body …" (Bartky, 1990: p. 35). In Bartky's view, within patriarchal societies, the woman is approached, or not, on the basis of her utility as a sex object, independent of other qualities that might make her attractive as a human being (Fredrickson and Roberts, 1997).

Martha Nussbaum (1995) identified seven dimensions of objectification: instrumentality, denial of autonomy, inertness, fungibility, violability, ownership, and denial of subjectivity. These dimensions are not simultaneously present in all cases of objectification: for instance, slaves are treated as goods, are sold and physically and psychologically violated, but, at the same time, are not considered as inert, because their physical activity establishes the slavery economy. For Nussbaum, instrumentality is the most dangerous dimension: when an individual is perceived as an instrument, he or she becomes useful and therefore interesting for those who intend to exploit him or her. Then, instrumental objectification implies approaching the objectified individual, a characteristic that distinguishes it from other forms of dehumanization, which usually involves the removal of the victim.

These different forms of dehumanization lead to different outcomes. As mentioned above, likening out-group members to animals implicates purposes of exploitation or intentions of mass killings; likening others to devils, monsters, or viruses leads to exacerbating the feelings of threat. Perceiving others as objects, instead, regards the world of commodification and instrumentality. It is also noteworthy that the same group may become the target of more dehumanizing images. For example, during the conquest of North America, the double portrayal of natives as savage beasts (i.e., wolves) and demons (i.e., red devils) led to the ethnic cleansing of the New World (Stannard, 1992).

The Legitimization of Evil: Research on Explicit Dehumanization

Psychosocial studies on dehumanizing processes documented how they are essential ingredients for social exclusion and atrocities: extreme negative behaviors toward a group perceived as hostile are facilitated when their humanity is denied. Thus, in contexts of intergroup conflict identifying dehumanizing attributes is particularly important because their presence is an indication of possible violent behaviors.

In social psychology, first theorizations about dehumanizing processes arose in the 1950s. Allport (1954) conceived

dehumanization as an extreme form of prejudice. In Allport's view, dehumanization concerns those individuals or groups perceived as outside the boundaries defined by ethical and moral values. Inspired by Allport's insights, Kelman (1973) and Opotow (1990) argued that dehumanization involves denying the identity of the victim, which is perceived as excluded by the social community where justice and solidarity are applied. When people are stripped of human qualities, they lose their capacity to evoke compassion and moral emotions, and may be treated instrumentally. When individuals or groups are included inside the boundaries of the moral community, they are treated fairly in resource distribution and in the sharing of sacrifices. On the contrary, the moral exclusion of individuals or groups by such boundaries rationalizes and justifies the perpetration of evil toward them. Thus, moral exclusion makes it normal and acceptable for acts of incredible cruelty toward others to take place.

This theoretical framework led to the first empirical studies. In particular, Bandura et al. (1975), by employing the electric shock paradigm, compared the punishment administered to dehumanized and humanized targets. (Electric shock paradigm was first used in the famous experiments conducted by Stanley Milgram (1963) on obedience to authority. In these studies, the experimenter ordered the participants to administrate electric shocks to another person – collaborator of the experimenter – whenever that person gave a wrong answer on a learning task. The electric shocks were fictitious. However, participants were not aware of this and believed to administrate painful shocks to another person.) Results showed that participants treated more punitively dehumanized targets than targets invested with human qualities. Based on these findings, Bandura (1999) developed the concept of 'moral disengagement.' According to the author, in the course of development people adopt moral standards that serve as guidelines for their behavior. In the face of situational inducements to behave in a reprehensible way, there are different mechanisms that shift the individuals' moral boundaries, and create a version of reality in which reprehensible conduct becomes morally acceptable. Mechanisms of moral disengagement operate, for instance, by cognitively reconstructing the behavior itself, by obscuring the agency of the reprehensible conduct, and by distorting or minimizing the consequences of the detrimental action. Dehumanization operates directly on the recipients of detrimental behaviors, which are blamed and perceived as beings that are not humans. Dehumanization is therefore a powerful process of disengagement from moral self-sanctions. To perceive another person as human arouses empathetic concerns. It is, therefore, difficult to mistreat him or her without feeling personal distress or remorse. If the other person is instead stripped of human qualities and emotions, if he or she is defined without human traits, the empathetic concerns are weakened and inhibited. For this reason, dehumanization is an essential weapon for anyone planning acts of extreme violence toward other individuals or groups. Exterminating, killing, and violating children, women, or men goes against the principles that each community teaches its members for the continuation of its existence, as well as perceiving itself as a complete community. However, at the time that material interests or unhealthy ideologies lead a group to exterminate another group, perceiving the out-group members as subhumans helps to go beyond the moral boundaries, and to enact behaviors that are unthinkable in a 'normal' context.

These assumptions have been corroborated by archival research on influential works of the nineteenth century. This research highlighted the obsessive use of dehumanizing metaphors regarding ostracized groups. For example, by following the theoretical framework of the delegitimization theory by Bar-Tal (1989), Volpato and colleagues (Durante et al., 2010; Volpato et al., 2010) conducted a series of studies analyzing the texts and the images contained in *La Difesa della Razza*, a bimonthly magazine of fascist propaganda, published between 1938 and 1943. Their studies documented the dehumanization of colonized people, who were likened to anthropoid apes. The dehumanization of the Jews was also particularly present in the images. They were portrayed in imaginative ways: they were spiders making their cobwebs on the world, snakes ready to attack, intellectuals writing with pens resembling vipers, chimpanzees posing as human beings, bats, vampires, vultures, parasites infesting the social body, monsters starving the humanity, or devils hiding their horns under a skullcap.

Psychosocial studies have mainly focused on the perpetrators, rather than on the victims. For example, the factors enhancing resistance to dehumanizing practices or the factors leading to acquiescence or internalization are still unknown. Furthermore, self-dehumanization processes remain unexplored. The analysis of Primo Levi's *If This Is a Man* represents the first attempt to investigate such phenomena. The goal of this work (Volpato and Contarello, 1999) was to explore the emotional, cognitive, and behavioral reactions of those who are excluded from humanity. In his book, Levi showed that in concentration camps, the dehumanization process deeply affected the self-perceptions of prisoners, who were forced to interiorize categories and pattern of thoughts imposed by the perpetrators. Throughout the book, Levi refers to a wider concept of dehumanization than the one commonly used in psychosocial studies. According to Levi, indeed, dehumanization concerns both victims and perpetrators because all the involved actors of the concentration camp universe were subjected to a tragic and often final impoverishment of their personality. Not seeing human in the other person destroys the humanity of both perpetrators and victims.

Throughout history, all the different expressions of dehumanization have been effective instruments of oppression and persecution. As discussed in the section below, powerful groups employ dehumanization for exploiting, humiliating, and destroying weaker groups.

The Functions of Dehumanization

Dehumanization mainly serves for (1) justifying group violence, (2) legitimizing the group's status quo, and (3) distancing individuals from potentially stressful events. Regarding the justification of intergroup violence, several studies have shown that dehumanization is an essential antecedent for marginalizing individuals or whole groups, and enacting violent behaviors toward them. Dehumanization decreases, and in some cases completely inhibits, feelings of empathy and compassion that individuals commonly feel

when observing others' sufferings. By doing so, dehumanization becomes useful for intentions of destruction and genocide.

For instance, recent works have revealed that after 9/11 dehumanization has been employed to develop consensus around the *war on terror*, leading Western public opinion to tolerate human rights violations and to neglect the impact of 'collateral damage' on civil populations. Terms like 'fighting enemies' or 'terrorists' have excluded enemies and prisoners from moral boundaries, and thus allowed international forces to treat them in ways forbidden by the Geneva Conventions. Steuter and Wills (2010) analyzed the dehumanizing metaphors used by Western mass media for describing the *war on terror*. They depicted the terrorist enemy through animal and biological metaphors – harmful animals, cancer, metastasis, viruses – that underscore the uncontrolled proliferation. Such metaphors serve for desensitizing the readers, and thus facilitate the approval of political and military decisions based on the denial of enemy humanity.

The second function of dehumanization concerns the legitimization of status quo. This function serves to reassure high-status group members about their social position, and makes them believe that they are immune from the bad luck of lower-status groups. In line with this reasoning, the attitudes exhibited by Western societies toward immigrants are particularly representative. For example, O'Brien (2003) listed an impressive number of dehumanizing metaphors used in the debate around restriction for immigrants entering the United States during the beginning of the twentieth century. The most representative metaphors recalled the objectifying nature of immigrants; they were seen as unassimilable and raw material, trash, and human derelicts. These objectifying metaphors were part of a rhetorical framework of instrumentality and commodification. These past figures of speech are repeated nowadays in many countries for delegitimizing immigrants.

The third and the least explored function of dehumanization serves for protecting those who hold power and control over other lives, and thus have to make potentially dangerous and painful decisions for other human beings. In contrast to the previous one, this function does not necessarily have negative effects on others, but instead it assumes defensive purposes. In this case, dehumanizing serves for distancing oneself from others. For example, it allows health care professionals (e.g., doctors, nurses) to manage and regulate their own negative emotions, above all when they are in particularly stressful and risky contexts (see Haque and Waytz, 2012).

The Hidden Side: Research on Subtle Dehumanization

A growing body of literature is disclosing the hidden side of dehumanization, and has documented the existence of less explicit forms of this phenomenon, which weaken the others' humanity in a subtle and unconscious way. These forms involve perceiving out-group members not necessarily as nonhuman beings, animals, or monsters, but rather as individuals who are only less human than in-group members. These subtle perceptions of lesser humanity occur even in the absence of intergroup conflicts; they pervade daily life without the social actor being aware of them.

Infrahumanization is the most relevant form of subtle dehumanization. Jacques-Philippe Leyens and colleagues (for a review, see Vaes et al., 2012) provided important evidence regarding this process. Infrahumanization is conceived as a subtle and unaware form of ethnocentrism (defined as the universal belief that one's own group is superior to other groups on a variety of dimensions, and at the same time that other groups lack a number of important characteristics, in the same dimensions, compared to the in-group); it does not imply a complete deprivation of others' humanity; it does not require the explicit likening of others to the animal world; and it does not lead to extreme reactions. Infrahumanization involves perceiving others as implicitly less human, without excluding them from social sphere.

Leyens and colleagues showed that people commonly use three characteristics to define human nature: intelligence, language, and sentiments. When perceived as lacking just one of these elements, groups are perceived as less human. The authors focused on the emotional aspect and, in particular, on the distinction between primary and secondary emotions (i.e., uniquely human emotions). This distinction derived from the concepts of 'emotions' and 'sentiments,' typically used in Romance languages. For Italian, French, or Spanish speakers, love is a sentiment and pleasure is an emotion. Emotions are affective states experienced by both human and animals, such as anger, fear, pleasure, and excitement. Sentiments are more complex affective states, which are thought to be uniquely experienced by human beings, such as remorse, nostalgia, pride, and hope. Primary emotions are part of human beings' gene pool, are universally shared, and occur earlier in the course of development. In contrast, secondary emotions are considered unique to human species, occur later in development, are not universally experienced in the same way, and tend to last much longer than the primary ones.

In an impressive series of studies employing different paradigms and instruments, Leyens and collaborators showed that people commonly attribute more secondary emotions to their in-group than to the out-groups, but do not differentially attribute the primary emotions. For instance, in one of the first experiments (Leyens et al., 2001), the researchers presented participants with a list of characteristics including primary and secondary emotions. The participants' task was to choose the characteristics that they considered typical of their in-group or typical of an out-group. The results confirmed the hypothesis that participants selected more secondary emotions for their in-group than for the out-group, whereas primary emotions were not differently associated with in-group and out-group. Importantly, the different association of secondary emotions was independent of the emotions' valence. In other words, it occurred both for positive and negative secondary emotions: participants even tended to attribute negative affective states to their group, in order to preserve its full humanness. Furthermore, such different associations emerged regardless of the group status. Out-group members are thus infrahumanized and perceived as less human than in-group members because they are considered as less capable of experiencing uniquely human emotions. Thus, results confirmed the existence of a 'privileged link' between in-group members and uniquely human emotions. A number of studies have also revealed that

infrahumanization has relevant consequences for intergroup relations, though milder than dehumanization. For example, a research study conducted 2 weeks after Hurricane Katrina documented that infrahumanization reduced the willingness to go to help the victims (Cuddy et al., 2007).

Why do people infrahumanize others? According to the theoretical framework of infrahumanization, the tendency to ascribe lesser humanity to out-group members stems from the universal inclination to essentialism. It refers to the people's tendency to perceive groups as natural entities, rather than as social artifacts built throughout the historical development of human species. Essentialism derives from a reification process whereby the differences between groups – commonly those differences that have important meanings in people's life – are interpreted as natural expressions.

Inspired by research on the infrahumanization-theory, over the past few years a growing body of research has explored the processes of subtle dehumanization by looking at a more general concept of humanity, which goes beyond the distinction between primary and secondary emotions (e.g., Boccato et al., 2008). In particular, Haslam and colleagues (for a review, see Haslam and Loughnan, 2014) have investigated these processes by considering human traits. They have proposed that humanness may be understood as characteristics that are uniquely human (e.g., rationality or morality) and define the boundaries between humans and other living beings, and characteristics that are representative of the core of human beings (i.e., traits of human nature), even though they are shared with other species (e.g., warmth or emotionality). Uniquely, human traits seem to implicate culture, social learning, or complex emotions; they refer to language, higher cognition, and conscientiousness; and they are learned during socialization and vary with the cultural context. Instead, human nature traits are innate, affective, universal, and implicate what is natural (Haslam, 2006). The denial of human nature traits leads to mechanistic dehumanization, while the denial of uniquely human traits leads to animalistic dehumanization. Research conducted in different countries highlighted that people in interpersonal relationships tend to attribute human nature traits of themselves rather than of the other person. In intergroup contexts, instead, people seem to attribute human traits congruent with the self-stereotype, whereas out-groups are attributed the less important human traits for the in-group's image. Further, in intergroup settings, the denial of human nature or uniquely human traits seems to have a distinct impact on willingness to help out-group members (Andrighetto et al., 2014).

Empirical studies on subtle dehumanization are now flourishing. Among others, Goff and colleagues' work (Goff et al., 2008) is noteworthy. It examined the persistence of historical dehumanizing representations (i.e., the 'Negro-ape metaphor'), which seem to have contemporary consequences operating beneath individuals' conscious awareness. Furthermore, the research from the 'ontologization perspective' (Pérez et al., 2007) is very relevant (this concept of ontologization suggests the idea that some ethnic minorities are more discriminated against than others. In particular, 'ontologization' refers to the representation of certain minorities outside the social universe of 'humanity'); it documented the persistent social exclusion of gypsies/Roma.

Objectification and Self-Objectification

Building on the objectification theory proposed by Barbara Fredrickson and Tomi-Ann Roberts (1997), a growing body of research has investigated the objectification processes (for a review, see Gervais, 2013). According to Fredrickson and Roberts, sexual objectification is described as the valuing of a woman exclusively on the basis of her body and on her sexual parts, rather than on her full identity. When a woman is sexually objectified, her body becomes a mere instrument for satisfying sexual male desires.

Although sexual objectification may assume different forms, the outcomes are often the same: women are ascribed restricted attitudes and roles, which reduce them to consumption objects, undistinguishable, interchangeable, and lacking in identity.

Furthermore, when objectified, women tend to adopt the observer's view and to treat themselves as objects to be looked at and evaluated. Self-objectification is the process whereby women and girls learn to think of themselves as instruments for others' desire. Historically, self-objectification derives from the female subordination typical of many societies, and from the fact that physical attraction has traditionally been one of the few means available to women for gaining power and social mobility. However, this strategy leads to focus on the physical aspect, neglecting other possible qualities. If objectification was maybe useful in the past, when women had few possibilities for avoiding the forced roles, nowadays it damages women and girls.

Self-objectification negatively affects psychological and physical well-being because it exacerbates negative emotions, reduces self-awareness, and contributes to mental and physical health problems, such as depression, eating disorders, or sexual dysfunctions. The first consequence of self-objectification is the increase of negative experiences concerning the body. The comparison with unreachable images of physical perfection, which are obsessively shown by the mass media, elicits sentiments of shame, disgust, and distress for one's own inadequacy. Such emotions produce mental stress and obsessive focus on the body, and lead individuals to a state of confusion that does not allow them to be clear-headed in their thoughts and actions. A further consequence of self-objectification is the decrease of the experiences of flow states, conceived as those moments in which a person, while performing an activity, is fully immersed in a feeling of being alive, and feels joy and satisfaction.

Several empirical studies have corroborated the objectification theory. These studies mainly focused on the relation between self-objectification, body image, eating behaviors, and intellectual performance (for a review, see Calogero et al., 2010). In particular, two empirical experiments by Fredrickson and colleagues (Fredrickson et al., 1998) opened the way for other studies. In their first experiment, the researchers manipulated self-objectification by having female participants try on a swimsuit or a sweater (depending on the experimental condition) in front of a full-length mirror. All participants were then asked to fulfill a questionnaire, eat some cookies, and have a drink. The results showed that women in the swimsuit condition reported lower self-esteem and felt more body shame, which in turn predicted restricted eating. The second experiment considered both male and female participants. The effects on body shame and restricted eating were replicated for women only, thus confirming the assumption that

self-objectification particularly concerns the female gender. Additionally, this experiment shed light on a further relevant outcome of self-objectification. After participants tried on the swimsuit or the sweater and completed the questionnaire, they were asked to perform a math test. The results showed that women in the swimsuit performed significantly worse on the math test than those in the sweater condition. No differences emerged instead for men. Such findings confirm the assumption that self-objectification consumes women's attentional resources, which is shown by their diminished mental performance on the test.

More recent works documented the progressive rise of objectification and self-objectification also among men, and highlighted the risk of these processes particularly for adolescents and children, who are increasingly subjected to the objectifying influence of mass media.

To date, psychosocial research has mainly focused on sexual objectification. In fact, in *Economic and Philosophic Manuscripts*, Marx put forward fundamental reflections on objectification and related processes of alienation within the work domain. The philosopher, when analyzing the alienation of worker's labor, argued that in the capitalism system work is not a free conscious activity, and therefore a manifestation of humanity, but rather it is an external imposition, depriving the worker of the product of his or her own work. Building on these reflections, some works are trying to extend the empirical analysis of objectification to the work context. In particular, the purpose of these studies is to explore whether the job, in certain circumstances, may lead workers to self-objectify themselves, and to be perceived by others as mere objects and instruments (see, e.g., Baldissarri et al., in press).

Recent Developments

Beside research on dehumanization and objectification, new research perspectives on denials of humanness phenomena are now emerging. In particular, works on anthropomorphism and on correlated neuropsychology of dehumanized perceptions seem particularly promising.

Anthropomorphism is conceived as the attribution of cognitive, emotional, and behavioral human characteristics to nonhuman entities, belonging to religious, natural, or technological spheres. Anthropomorphism has relevant psychosocial outcomes: perceiving agents as human indeed leads to considering them worthy of moral concern. Anthropomorphizing is a practice of humanization that likely leads to protect the anthropomorphized entities, by starting a process that is opposite to moral disengagement and exclusion (Waytz et al., 2010).

A further promising field of research refers to neuroimaging studies (a relatively new discipline in the field of psychology and employs different techniques or instruments (i.e., fMRI) evaluating functional aspects of neural activity), which explore the neural correlates of dehumanization. For example, Harris and Fiske (2009) found a relative lack of medial prefrontal cortex activation – a brain region hypothesized to be responsible for social cognition – after viewing photographs of social groups eliciting disgust and contempt (i.e., homeless people and drug addicts). Similarly, Cikara et al. (2010) found that pictures of sexualized women induce less activity in brain regions associated with mental state attribution, particularly for men with high ratings of hostile sexism. This is a relevant result suggesting that such out-groups are not primarily processed as human beings, but as objects.

At the present time, research on dehumanization is constantly evolving, and there will certainly be interesting developments in the next few years. Many issues still remain unexplored. For example, 'dehumanization for invisibility' should be explored, as a particular form of dehumanization practiced through silence, indifference, and the use of mere statistical numbers, which nullifies the salience of personal and social identity. This is a form of dehumanization integrating explicit and implicit elements; it stems indeed from the convergence of more explicit forms of dehumanization, which are primarily instilled by institutions, and more implicit ones, which allow society to not take responsibility for the deprivation of humanity of disadvantaged groups.

Another important issue concerns the identification of powerful strategies that inhibit dehumanization. To date, researchers have applied the same means commonly used for defeating prejudice and intergroup conflicts, such as intergroup contact (e.g., Andrighetto et al., 2012). Nevertheless, it is essential to identify specific strategies for contrasting dehumanization, since it is not only an extreme form of prejudice but also implies denying victims' humanity. However, what is clear so far is that dehumanization could be efficiently defeated only through the combined collaboration of institutions, policy makers, educators, and mass media, who must strive to recognize equal human dignity to all inhabitants of the Earth.

Abstract

Deindividuation is a characteristic of the individual in the crowd. It is a psychological state of decreased self-evaluation, causing antinormative and disinhibited behavior. The impact of deindividuation theory in science and society (especially twentieth-century politics) makes it one of social science's more influential contributions. Deindividuation theory is rooted in some of the earliest social psychological theorizing, more than a century ago. It seeks to explain the apparent transformation of rational individuals into an unruly group or crowd. It posits that the group provides an environment in which the individual – submerged and anonymous – suffers from a loss of self-awareness. Deindividuation hinders reflection about the consequences of actions, rendering social norms impotent while increasing suggestibility to random outside influences. Despite its status and impact, empirical support for deindividuation theory is minimal. Recently, this lack of support has been attributed to the faulty assumption that crowds cause a loss of self. Instead, research suggests that 'deindividuation' marks a transition from individual identity to social dimensions of the self. This transition to a social identity may increase responsiveness to social norms particular to the crowd, instead of decreasing responsiveness to generic social norms, as suggested by deindividuation theory.

The Psychology of Deindividuation

According to deindividuation theory, the psychological state of deindividuation is aroused when individuals join crowds or large groups. The state is characterized by diminished awareness of self and individuality. This in turn reduces an individual's self-restraint and normative regulation of behavior. In social psychology, deindividuation is a major theory of group behavior: it provides an explanation of collective behavior of violent crowds, mindless hooligans, and the lynch mob. In addition, deindividuation has been associated with other social phenomena such as genocide, stereotyping, and disinhibition in other settings such as computer-mediated communication (CMC). Later, the theoretical evolution of deindividuation is sketched, followed by a brief impression of the empirical support for this theory. Finally, recent research is discussed, which argues for a reconceptualization of deindividuation: It appears deindividuation is not a loss of individual identity, but may be better construed as a transition to a social identity.

Theoretical Evolution of Deindividuation

Deindividuation theory is rooted in the earliest works of social psychology, in particular Gustave Le Bon's (1895/1995) crowd theory (see Postmes and Spears, 1998; for a review). In his book *The Crowd*, Le Bon vividly describes how the individual in the crowd is psychologically transformed. He proposes that the psychological mechanisms of anonymity, suggestibility, and contagion transform an assembly into a 'psychological crowd.' In the crowd the *collective mind* takes possession of the individual. As a consequence, a crowd member is reduced to an inferior form of evolution: irrational, fickle, and suggestible. The individual submerged in the crowd loses self-control and becomes a mindless puppet, possibly controlled by the crowd's leader, and capable of performing any act, however atrocious or heroic.

Although Le Bon's theory has been extensively criticized, the influence of *The Crowd* in science and society is difficult to underestimate. The sales of this book are among the highest of scientific texts. In science, his analysis has inspired many theories of collective behavior, for example those of Freud, McDougall, Blumer, and Allport. In society, Le Bon's influence has been especially poignant: His theory also informed numerous politicians including Mussolini and Hitler, whose ideologies resonated with Le Bon's emphasis on racial factors (Nye, 1975).

The field of social psychology revived Le Bon's ideas in the 1950s. They were couched in more scientific terms as a theory of 'deindividuation.' Initially, it was argued that deindividuation occurs when individuals in a group are not paid attention to as individuals (Festinger et al., 1952). Thus, being unaccountable in a crowd or group has the psychological consequence of reducing inner restraints, and increasing behavior that is usually inhibited. The causes of deindividuation were gradually extended from anonymity in groups to other contextual factors, such as reductions of responsibility, arousal, sensory overload, a lack of contextual structure or predictability, and altered consciousness due to drugs or alcohol (Zimbardo, 1969).

Thus, although Le Bon's ideas were the blueprint for the deindividuation concept, the situations that cause deindividuation were gradually expanded to include other settings than the crowd. Deindividuation theory differs from Le Bon's theory in one further important respect: The consequence of deindividuation is not that the loss of individuality is replaced by a collective mind that guides the individual's actions. Rather, the loss of individuality leads to a total loss of self-awareness, and this incapacity for introspection releases a person from internalized moral restraints to produce emotional, impulsive, irrational, regressive, and intense behavior.

In the 1970s, deindividuation theory became a popular focus of scientific research, encouraged and inspired in part by the collective disorders characteristic of that period. However,

the empirical support for deindividuation theory was inconsistent. In particular, there was contradictory evidence regarding the influence of anonymity in groups, and there was virtually no evidence for the psychological state of deindividuation (Diener, 1980). Indeed, it appeared that this psychological state, which by all accounts appeared to be easily induced, was more elusive than initially conceived.

In response to these empirical obstacles, deindividuation theory was gradually modified and specified over the course of the 1980s. In particular, the psychological underpinnings of deindividuation have been narrowed down. In the original version of the theory, deindividuation was closely bound up with a lack of accountability due to submergence in the crowd. Thus, the focus was on anonymity in the group as the most important factor in producing deindividuation. But contemporary formulations of the theory shifted the focus to reduced (private) self-awareness as the central feature of deindividuation (Diener, 1980; Prentice-Dunn and Rogers, 1982). When one is self-aware, the focus of one's attention is on the (private) aspects of oneself, such as one's attitudes and norms. This self-focus is assumed to be required in order for people to self-regulate. But irrespective of whether anonymity or self-awareness is the crux of deindividuation, both classical and contemporary perspectives argue that deindividuation leads to antinormative and disinhibited behavior.

In more recent years, the phenomenon of deindividuation has been applied to social behavior on the Internet. Kiesler and colleagues proposed that disinhibited behavior in CMC could be accounted for by anonymity (Kiesler et al., 1984). Based on deindividuation theory, it was argued that visual and auditory anonymity of online interaction partners masked both personality and culture. In a mixture of elements from classical and contemporary deindividuation theory, this was hypothesized to reduce self-awareness and depersonalize one's audience, causing deregulated and antinormative behavior (Kiesler et al., 1984; Siegel et al., 1986).

Deindividuation Research

Several influential studies were conducted to illustrate the force of deindividuation. For example, Zimbardo (1969) reports a study that inspired much subsequent deindividuation research. In one study, participants were rendered anonymous by clothing them in oversized lab coats and hoods, compared with normal clothes and name tags in the control condition. The participants' task was to shock a confederate in a situation similar to the classic Milgram studies on obedience. In a first experiment using groups of female students, Zimbardo demonstrated that anonymous participants shocked longer (and therefore more painfully) than identifiable participants, in confirmation of his theory.

Aware of the limitations of Zimbardo's research in terms of external validity, Edward Diener and colleagues devised more naturalistic contexts in which to test the theory. In some studies, groups of participants were required to 'test' a so-called pacifist, trained to remain nonresponsive, by hitting the pacifist with foam swords and so forth. The researchers claimed this provided a measure of aggression that was more ecologically valid for crowd behavior. Results were inconsistent, however. In one study, for example, isolated individuals displayed more aggression than groups did (see Postmes and Spears, 1998 for a review).

In another study, Prentice-Dunn and Rogers (1982) induced deindividuation by instructing participants repeatedly to focus attention outward. In addition to attentional focus, participants were seated in a dimly lit room with loud rock music playing, verbal interaction was encouraged, and the groups played exciting video games. In contrast, participants in an internal attention focus condition were told not to interact, performed individual tasks, and played nonarousing games in a well-lit quiet room. Results showed that when attention was focused outward, higher levels of aggression were obtained.

More recently, deindividuation research expanded into the realm of CMC. Anecdotal reports of early CMC usage suggested that users were more likely to be disinhibited when they interacted online. Some initial studies appeared to confirm this. Siegel et al. (1986) conducted an experiment studying three-person groups who were presented with a choice-dilemma and asked to reach consensus. These decisions were made face to face, via an anonymous CMC system, and via a nonanonymous CMC system. Consistent with deindividuation theory, interactions via a computer exhibited both more polarized opinions (i.e., more extreme shifts away from members' initial choices) and more disinhibited and aggressive behavior than face-to-face communications.

But in CMC there was also conflicting evidence regarding the fundamental processes thought to promote deindividuation. In their empirical investigation of self-awareness in CMC Matheson and Zanna (1988) showed that, relative to face-to-face interactions, CMC showed significantly higher levels of private self-awareness – a finding opposite to deindividuation expectations. Thus, there was mixed evidence regarding deindividuation in CMC.

Support for Deindividuation Theory

These examples illustrate that empirical investigations of deindividuation theory searched for evidence of deindividuation in ever more exotic social situations. Although several studies show effects that appear to be consistent with deindividuation theory, many studies failed to support it, and many reported contrary results. For example, Zimbardo's (1969) original paper reports that a replication of the study mentioned earlier obtained the exact opposite results. Also in the case of CMC, evidence was inconsistent. In contrast to some positive findings (Siegel et al., 1986), there are other studies showing that online anonymity can sometimes promote more conservative, cautious decisions and prosocial behavior (e.g., Hiltz et al., 1989). Thus, evidence for deindividuation theory appears to be mixed. A meta-analysis of the deindividuation literature confirms this impression. This study examines 60 tests of deindividuation theory and concludes that there is insufficient support for deindividuation theory (Postmes and Spears, 1998). Disinhibition and antinormative behavior are not more common in large groups and (crowded) anonymous settings. Moreover, there is no evidence that deindividuation is associated with reduced self-awareness, or even that reduced self-awareness increases disinhibition.

Overall, then, deindividuation theory does not receive sufficient empirical support.

Reconceptualizing Deindividuation

One likely reason for the lack of support for the deindividuation concept is that the theory is based on Le Bon's characterization of the crowd, which is fundamentally flawed. According to Le Bon, collective behavior is always irrational: the individual in the crowd loses cognitive control. Deindividuation theory accepts this notion. For example, Diener argued that crowd members are "similar to the stimulus-response organism of early behaviorism, with reduced conscious mediation" (1980: p. 230). This negative and disorderly view of collective behavior stands in stark contrast to historical analyses of the crowd, which stress the crowd's capacity for restraint and orderly behavior (e.g., Rudé, 1964). Moreover, these historical analyses accentuate that the crowd often acts on the basis of moral principles and popular consensus (see also McPhail, 1991). Thus, a compelling case can be made that collective behavior is not unrestrained (as argued by deindividuation theory) but rather restrained by normative processes. The implication is that collective behavior is under conscious control, and far from irrational and unrestrained.

Recent social psychological research supports such a normative analysis of collective behavior. In deindividuation studies, for example, people are more likely to follow local group norms in situations where they are anonymous or where self-awareness is low (Postmes and Spears, 1998). The idea that behavior could be the result of local group norms was considered explicitly by Johnson and Downing (1979) who showed that the effects of anonymity depended on the normative cues in the environment. Participants were made anonymous by means of mask and overalls reminiscent of the Ku Klux Klan (similar to Zimbardo's uniforms) or by means of nurses' uniforms. Although compared to the control condition participants shocked somewhat more when dressed in the Ku Klux Klan uniforms, they actually shocked less when dressed as nurses. This finding illustrates that groups are sensitive to normative cues associated with the social context. Similarly, in CMC the phenomenon of online flaming has been interpreted as a locally normative behavior which may be experienced positively within specific subcultures (Postmes et al., 2000).

This finding that crowds act normatively, prompted a reinterpretation of the effects found in deindividuation research. The Social Identity Model of 'Deindividuation' Effects (SIDE; Reicher et al., 1995) uses social identity processes to explain deindividuation phenomena. Central to SIDE is the idea (derived from self-categorization theory) that there is not one unitary self-concept, but rather that the self is multifaceted. Specifically, the self contains not just one's personal identity (i.e., the unique part of the self), but is also composed of many different social identities which the individual shares with groups of others (Reicher et al., 1995). SIDE argues that conditions of anonymity (or CMC) do not cause a loss of self, but that they can shift a person from an individual identity to a collective identity, provided that people are members of the same group or crowd. For example, being in a demonstration will accentuate the unity of participants if they rally behind their cause – seemingly oblivious to strong divisions and disagreements that may exist between them. This common group membership may become accentuated if an opposing group (such as the police) acts upon the crowd as if it were one, for example by blocking its way or attempting to contain it. The strong adherence to this common group membership, which emerges over the course of such events, explains why normative regulation within the crowd may occur (Reicher, 1987).

Thus, whereas deindividuation theory argues that the crowd causes a loss of identity, leading to disinhibition, SIDE argues that the crowd causes a shift from a personal identity to a social identity (shared with the crowd) leading to social regulation of behavior. This may explain the normative restraint within the crowd as observed by historians, as well as the normative restraint observed in experimental studies of deindividuation.

Although the SIDE model originated as an alternative perspective on crowd behavior, it was also applied to normative regulation online. Processes described in the SIDE model revolve around the psychological rather than physical presence of one's group. This means that the SIDE model can be applied to contexts in which others are co-present (such as crowds) just as easily as situations where others are not co-present (such as CMC). In order to understand online 'deindividuation effects' we need to first understand whether communicators think of themselves as an individual or a group member. Online, there are many contexts in which personal identity is likely to be salient. Under such conditions, when the self is thought of as unique and different, the SIDE model argues that online anonymity provides people with the means to follow personal standards and norms. But there are also many online situations in which a clear social identity is available and salient. Under such conditions, anonymity and the physical absence of others can paradoxically amplify the influence of the group and its norms. This is because individual group members (and their idiosyncrasies) are not visible, so all that remains is the unifying idea of 'us.' CMC is therefore an unlikely but fertile forum for the growth and expression of social identities, facilitating increased group cohesion and commitment (and thereby, SIDE foreshadowed the social side of Internet). Thus, according to SIDE, computer-based interactions do not lead to a loss of self, but amplify it. CMC provides the cognitive conditions which allow greater freedom to be true to the personal self, as well as to their group.

In sum, there is no consistent empirical evidence that supports deindividuation theory either in real-life groups and crowds or in online behavior. There is no consistent relation between anonymity and disinhibition. It appears to be more productive to think of deindividuation not as a loss of self, but as a shift to a different aspect of the self and the norms associated with it. In the case of the crowd, this means a shift from personal to a shared social identity. Online, in situations where people interact with others of the same group, a similar accentuation or shift toward a shared social identity can be found. The ability of SIDE to explain diverse phenomena – including behavior in the presence and absence of others – attests to its utility. Ultimately, this reconceptualization emphasizes that explaining deindividuation phenomena as a loss of self is too simplistic. Diverse social and cognitive phenomena come together to influence the norms that people respond to in different contexts. There is no evidence of a loss

of self in the crowd. Rather, the crowd provides individuals with an avenue for the expression of collective identities, directed and inhibited by social norms.

Deinstitutionalisation in Low and Middle Income Countries

Julian Leff, University College London, London, UK; Kings College London, London, UK; and University of Cape Town, Rondebosch, South Africa

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The progress achieved in transforming a psychiatric-hospital-based service to one based in the community is reviewed, comparing the United States with the United Kingdom. The situation in low- and middle-income (LAMI) countries is considered in terms of the history of psychiatric services, including the role of colonialism. Statutory psychiatric resources in a number of LAMI countries are enumerated. Innovative examples of the provision of psychiatric care in the community in countries with scanty resources are described, augmented by the author's investigative visits to many of them. The lessons to be learned from these experiences are summarized in an overview.

Institutionalization in High-Income Countries and Low- and Middle-Income Countries

While deinstitutionalization in the USA and Western Europe has been relatively successful, with a few exceptions this is not the case in low- and middle-income (LAMI) countries. In England and Wales, the number of functioning psychiatric hospitals has fallen from 130 in 1975 to less than 12 today, (Leff, 2000) having been replaced by a variety of community-based services including community mental health teams, crisis teams, day hospitals, and day centers and a number of alternatives to hospital admission, such as acute day hospitals, and crisis houses (Johnson, 2010). The change in the location of psychiatric care has not been so dramatic in the United States with a less comprehensive network of community services. However, large psychiatric hospitals began to close in the 1950s. In 1955, there was 1 psychiatric bed for every 300 Americans. Currently, there is 1 for every 3000 (Torrey et al., 2010). The situation is quite different in LAMI countries, but varies considerably from country to country, depending on the development of their psychiatric services. The state of mental health services in LAMI countries will be discussed with examples from a variety of countries with different levels of economic development and of service provision. Between them they present a wide range of solutions to the problems of deinstitutionalization, which are instructive.

Ethiopia and Egypt

Ethiopia with a population of 80 million has only a single psychiatric hospital with 250 beds, situated in the capital and staffed by 17 psychiatrists who have received training from a team from Toronto. In the rest of the country, new psychiatrist-led units have been established in four cities, and nurse-led psychiatric units are scattered around the country. Otherwise, the only resource available is the Coptic churches that provide treatment for mental illness with holy water and by beating the patients to drive out evil spirits. By contrast, Egypt, with the same population size as Ethiopia, has 15 state psychiatric hospitals with 7000 patients, 60% of whom have been resident for 5 years or more. Outpatient services are hospital based with no community input. There is 1 psychiatrist per 80 000 population, 1900 psychiatric nurses, and around 200 clinical psychologists. A collaborative agreement between the Egyptian government and the government of Finland initiated a Mental Health Program in 2002, with the aim of moving the locus of care from the psychiatric hospitals to the community. However, this objective has not been achieved to any significant degree. One important outcome has been the ratification of a Mental Health Act in May 2009 (Loza, 2010). In countries without an act of parliament protecting the rights of mentally ill people there can be no recourse for inhumane treatment. Furthermore, such an Act raises public awareness of the plight of mentally ill people in degrading and humiliating institutions.

Chile

Chile after Pinochet has the superficial appearance of a European country with civilized standards. However, it does not have an operational mental health act. Professor Martin Cordero, a senior Chilean psychiatrist who worked in the United Kingdom for 10 years, was commissioned by the Chilean government to draft a mental health act. He prepared a comprehensive document and submitted it several years ago. It has never been enacted by the parliament. As a result, according to World Health Organization (WHO) Chile does not have a mental health policy. The neglect and abuse in psychiatric institutions that persist as a result were conspicuously evident to me on a visit to the University Psychiatric Hospital in the southern city of Conception. As I walked through the wards I noticed piles of sand lying in various places. I was curious about their function and was told that the roofs leaked for lack of funds for repairs and the sand absorbed the rainwater. I also noted that the television sets on the wards were too high up for the patients to reach the controls. Only nursing staff could change the channels. Worse was to come. I entered a ward for female patients, which was adjacent to a ward for long-stay patients with tuberculosis. The women were all nursed in their nightgowns. Their toilet was a very large room with many holes in the floor in place of proper lavatories, and the entrance door was rotting at the bottom leaving a wide

 http://dx.doi.org/10.1016/B978-0-08-097086-8.27081-5

gap. I found it incredible that conditions of this kind could persist in an institution belonging to a university.

Professor Cordero advised me to visit the forensic hospital in Santiago de Chile. The entrance was guarded by two soldiers with rifles. The director proudly showed me his up-to-date leucotomy unit. On questioning he informed me that they performed three leucotomies per week, and that the patients receiving this treatment were suffering from substance abuse, psychopathy, and anorexia nervosa. I asked if the patients gave their signed consent for this procedure, and he replied that it was sufficient for the parents to give their permission. I reported this back to Professor Cordero, who made representations to the Mental Health Department. He was astute enough to base his argument for closing the unit on the large expense of maintaining the unit and the absence of evidence for its effectiveness. This led to the closure of the unit, whereas the human rights issue would almost certainly have failed. Pinochet casts a long shadow.

Mexico

In LAMI countries with faltering economies it is not unusual to find psychiatric hospitals with degrading conditions alongside innovative community initiatives that mobilize local resources with excellent results. Two colleagues and myself were commissioned by the WHO to conduct a survey of mental health services in the administrative region of Mexico City, after the Director of mental health services announced his plan to build 100 new psychiatric hospitals. In one hospital we visited there were two buildings. One was a closed ward for long-stay patients with a solid steel door. The Director proudly informed us that this was a state-of-the-art ward designed by an architect and based on Jeremy Bentham's concept of the panopticon. The ward was circular with the beds arranged around the perimeter of the circle, and a nursing station in the center allowing full visibility of every patient at all times. A consequence of this arrangement was that there was no room between the beds for cupboards to contain the patients' belongings.

Across the way from this immaculate building was a decrepit ward housing patients with psychoses together with patients with severe learning difficulties. At the back of the ward were the lavatories in an open space behind a low brick wall, which allowed visibility of the patients using the facilities. Only the nursing staff had access to the flushing system for the lavatories.

In extreme contrast, our next visit was to the town of Tierra Colorada. We were ushered into the Primary Care Health Center where we were given an enthusiastic welcome by a large group of children and adults of all ages. They presented programs of instruction in mental health care, which are delivered by volunteers from the appropriate age groups. Thus there are child volunteers (Agentes Juveniles en Salud – Young Health Activists), adolescents, adults who address mother–child issues, others who assist parents, and health activists of the third age. The Young Health Activists use puppets in their educational sessions with children. By this means, all age groups receive mental health education from their peers. This was a striking example of what can be achieved with very little expense to reach out to local communities when official mental health services are restricted to inappropriate buildings with institutionalized patients and staff.

Iran

A somewhat similar approach to developing community psychiatric services has been initiated in Iran. A national program has been mounted of training primary health care workers and local community workers. At least one male and one female *behvarz* (a local person from the same village) work in each 'health house.' *Behvarzes* have a general education up to secondary school level and 2 years training in health care, including 1 week of formal training in mental health. This program has been rolled out nationally through effective central control. The expansion of mental health care into primary care has reduced assistance sought from traditional practitioners. Across several areas, first contact with a traditional health practitioner for a mental health problem has shifted from 40% in 1990 to 16% in 2000.

Jamaica

The transformation of psychiatric services in Jamaica was achieved through the vision and dedication of the Professor of Psychiatry in the University of the West Indies, Frederick Hickling. As in many of the Commonwealth countries, the sole psychiatric hospital, Bellevue, was built by the British. It was opened in 1861 and originally named Kingston Lunatic Asylum. By 1945, the number of beds had increased severalfold to 2350, resulting in overcrowding, as happened in the mental hospitals built in the same period in Britain. From 1974 determined efforts were made to shift the locus of care away from the institution by developing a community mental health system. Currently, there is a network of over 300 clinics providing a full range of mental health services, delivered primarily by mental health nurses, supervised by 30 psychiatrists. More than 40 000 patients are treated annually (Hickling, 2010). As a result of this development, the number of beds in Bellevue has dropped to 700. There is a mobile community follow-up service that keeps track of the hundreds of patients who have problems with medication adherence, and provides emergency services, crisis intervention, and acute hospitalization when necessary. More than 60% of those patients requiring hospitalization for acute mental illness are admitted to the medical wards in general hospitals. There is a mountainous region in the center of Jamaica, which renders travel to and from Kingston difficult for patients. During a visit I made to the island, I accompanied a mental health nurse on her regular drive up into the mountains to visit the wooden cabin there, which is used as a dispensary for patients living in that region to collect their psychotropic medication.

South Africa

In 2013, South Africa had its financial aid from Britain discontinued because of its increasing general affluence. However,

there is still a very large section of the population that lives in poverty in makeshift shacks. The psychiatric services exhibit the same patchy quality ranging from sophisticated university departments of psychiatry to no services at all. The history of South African psychiatry begins with Robben Island, where Nelson Mandela was imprisoned. In 1845, the prison colony on the island was converted to a leper colony, and later to a psychiatric hospital. It is interesting that the same change in use occurred on the Finnish island of Sela. In 1910, there were eight government mental hospitals caring for 3624 patients. A Mental Disorders Act was introduced in 1916. By 1955, there were 13 mental hospitals with 17 881 patients. Currently, the population of 52 million is served by 24 public psychiatric hospitals, accommodating 14 000 acute and long-stay patients. There is 1 psychiatrist per 350 000 population, 1 psychologist per 312 000, and 1 social worker per 250 000. However, there are no community psychiatric services in the North West and Northern Cape. The problem of providing any kind of health services to this sparsely populated region has been tackled in a highly innovative way by means of the Health Train. This project began in January 1994 and has brought health care to rural areas where there is 1 doctor for every 4000–5000 patients. The train brings a variety of health specialists to remote areas where most people have no access to specialized services. The train travels around the country for 36 weeks of the year, stopping at least five times at each of the 36 stations in three rural regions. Initially the train had three carriages and was solely financed by Transnet, the railway services company. It expanded to 16 carriages and many companies now act as sponsors. About 40 000 patients receive treatment from the specialists on the train each year and well over 1 million people have been treated to date. The train has an Edu-Clinic, which is equipped to teach groups of 25 volunteers about basic health issues; a medicine clinic with a pharmacy; a dental clinic; and an eye clinic. Initially no psychiatric service was included, but the train now has a psychology clinic with two consultation rooms. This innovative outreach service provides mental health care to the poorest and most remote of the rural poor.

Where there is no possibility of accessing sophisticated psychiatric help, many people consult traditional healers (Behr and Allwood, 1995). It is a mistake to dismiss this source of help as worse than useless. Prince (1960), who worked as a government psychiatrist in western Nigeria, discovered that traditional healers were treating psychotic patients with a preparation from the plant *Rauwolfia serpentina*, which has an antipsychotic effect, and was recommended for mental disturbances in the Ayurvedic writings of India, which date back more than 2000 years (Leff, 1988). Aside from herbal treatments, some healers are acute observers of people and can employ psychological understanding to determine the cause of their problems. Harvey (1976) describes the traditional Korean healers as "keenly intuitive and perceptive persons who make good use of their knowledge of people and human problems in helping their clients make the best of their situations. They give conservative advice, provide clients with outlets for potentially disruptive emotions, and get substantial help from the passage of time in solving clients' problems." I interviewed Mr. Gepe, a traditional healer in Gugulethu, a township in Cape Town, whose abilities accord with Harvey's description. Mr. Gepe told me, "I am sitting in my house when three men appear at my door. They stand there silent. I have to be able to say to them, 'You have come to me to help you find the oxen you have lost.'" There is nothing magical about his intuition. The men are in tribal dress and are obviously herders. As there are three men together it cannot be a domestic problem. That narrows down the possibilities. The South African government is well aware of the yawning gaps in the services, but is also cognizant of the fact that among traditional healers there are quacks and con men as well as people of integrity. Therefore they have initiated the process of registering traditional healers with the aim of excluding the undesirables.

Under the former apartheid government, racial segregation was the rule in all hospitals, including those for psychiatric patients. Nonwhite nurses were forbidden to treat white patients. The enlightened director of Valkenberg psychiatric hospital in Cape Town, Professor Lynn Gillis, subverted this law, taking a risk with his career. That law no longer pertains, but the legacy of the inhumane doctrine of apartheid has left its traces, which are evident in the educational system at all levels; for example Stellenbosch University is training 2000 psychologists, only a handful of whom are nonwhite.

The investment over the years in a relatively large number of psychiatric hospitals and the stultification generated by the apartheid system has severely impeded the transition to community-based psychiatric facilities. For several years I acted as an advisor to the planning committee for psychiatric services in Cape Town. The members listened to my arguments for deinstitutionalization and responded positively. But it was not possible to make plans with any confidence as the government failed to provide any funds for this transition. Instead money was made available to upgrade the acute admission wards. In the event, the building work was so shoddy that it had to be pulled down and the process begun again. Currently, the plans being discussed are to rebuild much of Valkenberg hospital, an unfortunately retrograde decision.

In the absence of government investment in the much-needed community services, voluntary organizations have stepped in to bridge the gap. Rotary has provided funds to create rehabilitation facilities on the site of a small psychiatric hospital. These include the creation of a horticultural center maintained by patients with learning difficulties, and some sheltered residences on the boundary of the hospital. Another nongovernmental organization (NGO), The Cape Mental Health Society, holds regular meetings for staff, patients, and family carers to exchange experiences and to learn from each other better ways of managing daily problems. There is a branch of Fountain House in Cape Town that provides excellent work experience for psychiatric patients in the community.

China

While the transformation of the Chinese economy created a wealthy stratum of society, many people were left in relative poverty. Hence China can still be included among LAMI countries. The investment in health services went mainly to the big hospitals, and primary health care, including care for psychiatric illnesses, was largely neglected (Li et al., 2005). The government's intention to develop community health care was impeded by the lack of training of staff in mental health care,

poorly equipped clinics, and the absence of health insurance cover for community mental health services except for medication and hospitalization. Phillips et al. (2009) estimated that of moderately or severely disabled patients with a psychiatric illness, only 8% have ever sought professional help, and only 5% have ever seen a psychiatric professional. In 2005, the trial known as the '686 Program' started to explore a service model for people with psychoses integrating hospital and community services. It has now spread to 112 sites with a catchment population of nearly 100 million (Ma et al., 2009). The process of transition to a community-based mental health service faces several obstacles: most Chinese psychiatric institutions are isolated from mainstream medicine, both academically and geographically, and the training curriculum for psychiatrists is mainly biological. It is noteworthy that until recently there was no Chinese word for unconscious.

On a visit to China 15 years ago, I was taken by my hosts to a remote rural area to see what was available for psychiatric patients. The small building I entered was dark and poorly furnished with a number of cell-like rooms and had no recreational facilities. On the other hand, the local village pharmacist we next visited raised my spirits. The pharmacist had been trained in the use of three medications, an antidepressant, an antipsychotic, and carbamazepine, which he used both to stabilize the mood of bipolar patients and to treat epilepsy, since it is active in both conditions. I asked him through the interpreter how many patients he sent to the nearest psychiatric hospital each year, and his answer was one. The ingenuity of this solution combined with strong central control, and a massive work force gives hope that China has the potential to create a modern psychiatric service firmly based in the community.

India

At the time of independence from Britain, India had almost no mental health services. There were psychiatric hospitals built by the British, such as the hospital in Agra, staffed by two psychiatrists and serving a population of 4 million. The whole country had 10 000 psychiatric beds for a population of over 300 million. In the first two decades after independence, the number of mental hospital beds was doubled and hospitals were humanized. Dr Vidya Sagar in Amritsar introduced the innovatory practice of encouraging the active involvement of families in the care of their relatives in psychiatric hospitals. The introduction of psychiatric admission beds into general hospitals was the next destigmatizing effort, which took place slowly. In 1975, there was a new initiative to integrate mental health services with general medical services in the community. Four decades later, this integration has been achieved in over 127 districts, representing 20% of the population. In 1982, The National Health Program was formulated to develop a national-level initiative for mental health care based on the community psychiatry approach. This led to the provision of many day care centers, half-way homes, long-stay homes, and rehabilitation facilities.

Despite these positive developments, a large number of people remain untreated, with a greater proportion in rural than urban areas, as was found in China. A major barrier to the use of services is the high level of stigma attached to mental illness, affecting social relationships and even more so employment. In addition, there are many different belief systems, some religious, others pertaining to traditional medical lore, such as Ayurveda and Unani. On visiting the Agra psychiatric hospital, I asked Dr Dube, the director, whether many of his patients consulted traditional healers. He replied that there was a temple of Hanuman, the monkey god, some distance from the hospital. Hanuman is consulted by many people for mental health problems. He went on to say that half the patients admitted to his hospital, had first been to the Hanuman temple. He added, "of course I only see the failures of the temple!" Traditional practitioners are not invariably antagonistic to Western medicine. I interviewed a traditional healer in a village near the Post Graduate Medical Research Institute in Chandigarh, in the Punjab. I discussed with him his treatment of depression. He used mainly psychological methods, sometimes in combination with herbs, but if these failed he told me, "I send the person to the hospital for electroconvulsive therapy (ECT)."

The legacy of the British Raj has been difficult to eradicate. A survey of mental hospitals was conducted in 1998 and found a catalog of the worst aspects of institutional care, including overcrowding, floor beds, complete lack of privacy in the use of toilets, isolation cells, deteriorating structures, and lack of trained staff. The report concluded that the rights of the mentally ill are grossly violated in mental hospitals. The problems are not confined to the institutions. Recent studies have revealed that about half the people with schizophrenia are living in the community without treatment, imposing a heavy burden on their families. Taking India as a whole, there are considerable deficits in the number of trained psychiatrists, psychologists, psychiatric social workers, and psychiatric nurses working in hospitals. These deficits are uneven across the regions with a few having adequate staff, and many with gross deficiencies. The 1998 report stimulated the provision of funds to improve conditions in the mental hospitals. A follow-up report in 2008 documented many positive changes, including reductions in admissions through courts from 70 to 20%, long-stay patients from 90 to 35%, and use of cells from 20 to 8 hospitals. In addition, there had been an increase in hospitals with recreational facilities from 8 to 29, and hospital with rehabilitation facilities from 10 to 23. Despite these progressive changes, the shortage of skilled staff persisted. The government's response was to provide generous funding for educational programs across the mental health care spectrum. In itself this did not tackle the problem of establishing a range of psychiatric facilities in the community. This deficiency was addressed by many NGOs, which have established day care centers, half-way homes, long-stay homes, and school and college mental health programs. Voluntary organizations can provide such services in a user-friendly way ensuring their acceptance by local communities. During the past decade, families have been playing a more active role with the formation of self-help groups, and professionals have been agreeing to work with families in a partnership model (Murthy, 2011).

There is no doubt that the new Indian Government of 1947 faced an enormous task in tackling the inhumane conditions in the psychiatric institutions built by the British, and in providing a comprehensive community psychiatric service for a vast and scattered population with inadequately trained personnel. They have made great progress in improving the conditions in the

outdated institutions, and in this area they are ahead of China. They have attempted to upgrade the specialist workforce, with moderate success, but have yet to mobilize the resources to create a functioning community alternative to institutional care. Instead, as happens in Western countries as well, the gap in services has been partially filled by voluntary organizations. However, the government has an obligation to ensure that they do not shirk their responsibility to consider the needs of the most disadvantaged citizens, leaving it to the goodwill of volunteers with limited resources to make up the deficiency.

Overview

From the examples presented it is obvious that the strategies required to create a well-functioning community psychiatric service depend on the previous history of psychiatric care in each country. In the United States and Western Europe the history of the building of psychiatric institutions is very similar, and by and large so is the availability of trained psychiatric staff. Hence the problems of transition to a community-based service do not differ dramatically. However, if we take the situation in Ethiopia, it might be considered fortunate that the authorities have only to phase out a single psychiatric hospital. However, the fact that only 17 trained psychiatrists are available for a population of 80 million stresses the magnitude of the tasks facing the government of a country still emerging from the effects of the murderous regime of the Derg, and among the 10 poorest countries in the world. I did see one hopeful sign of progress during a visit in 2010 when I was taken to a rural site on which an Italian construction company was building a very well-designed residential rehabilitation unit. However, when I asked the manager how long patients would stay in the unit, his answer was 'indefinitely.' It would be conceivable for Ethiopia to learn from the strategies of Tierra Colorada in Mexico and from Iran and train local people to become educators of their neighbors in mental health issues, a low-cost solution. It would not be feasible to integrate traditional healers into the psychiatric work force as in South Africa, since holy water and beatings are useless as treatments for psychoses, although holy water might exert a placebo effect on mild neuroses.

Egypt was showing signs of positive changes in its psychiatric services until the recent 'Arab Spring' and it is difficult to foresee any further progress until the political situation stabilizes. Fundamentalist governments that discriminate against women are unlikely to take a stand against the stigma of mental illness. The inertia of the Chilean government in taking the first step of humanizing its psychiatric hospitals does not inspire hope of change there. Jamaica is a shining example of how a colonial legacy can be transformed, but needs a charismatic leader like Professor Hickling to see the process through. The ingenious solution of the South African Health Train might be replicable in other LAMI countries with scattered rural populations, but would need the goodwill of the railway companies to kick-start it.

The two population giants, China and India, have different histories and therefore different trajectories. India has made admirable progress in emerging from its situation as a British possession, but its intention to create a well-functioning community-based psychiatric service is a daunting task in a subcontinent with a multitude of different ethnic groups, languages, and systems of treatment, and a caste system with ingrained stigma. China has shown its capacity to successfully transform its social structure, and given the will, could rectify the poor conditions in rural area where half the patients with psychoses have never received any treatment. However, it requires a government that can place the treatment and care of people with psychiatric illnesses high up its list of priorities. The argument presented by the WHO that mental illness incurs a very large cost to a country in terms of lost ability to earn a living and the financial burden on family carers should be an inducement. Voluntary organizations in almost every country have filled the gaps in the services for mentally ill people, and have done this very well. However, the experience in the United Kingdom has demonstrated that the determination of successive governments to carry through a policy of deinstitutionalization is crucial for the success of this humanitarian endeavor.

Acknowledgment

I am deeply indebted to Dr R. Srinivasa Murthy for sending me his paper on the development of psychiatric services in India.

Abstract

The spread of asylums throughout Europe and North America is charted and the use of asylums to contain the rejects of society described. Figures are given showing the peak bed occupancy in various countries and the fall in beds thereafter. The turnaround is ascribed to the effects of World War II on military psychiatrists, the introduction of antipsychotic medication, public scandals around the abuse of patients, and sociological critiques of institutions. Political backing for the transition to community psychiatry is discussed with particular reference to the situations in Italy and the UK. Community services developed for the long-stay patients are described and the results of some long-term follow-ups presented. Attention is drawn to the barriers to social integration of patients in the community, and to the lack of job opportunities. The costs of hospital and community care are presented from two studies and the need for cost-benefit analyses stressed. Critiques of deinstitutionalization from professionals, the media, and the public are discussed, with a focus on issues of violence by patients, imprisonment, and homelessness. The distinction is drawn between services for the long-stay and for the acutely ill, and the need for a comprehensive service is emphasized.

The term 'deinstitutionalization' is a somewhat cumbersome shorthand for the process that has occurred in North America and Western Europe of shifting the locus of psychiatric care from the large dedicated psychiatric hospitals to the districts in which people live. In order to appreciate the impetus behind deinstitutionalization, it is first necessary to review the reasons for the establishment of asylums. The rundown and closure of the asylums raises fundamental questions about the attitudes of the public to the mentally ill and the nature of 'the community.'

The Rise of the Asylum

One of the oldest psychiatric institutions in the West is the Bethlem hospital, founded as a priory in 1247 and used to house the mentally ill from 1403 to the present day. Its name, corrupted to Bedlam, attracted the stigma that became an inescapable feature of such institutions and was used to vilify the psychiatrically ill as bedlamites. Similar hospitals were established throughout Europe and North America in the ensuing centuries but the massive expansion of psychiatric hospitals, or asylums as they became known, did not occur until the nineteenth century. In the UK, this was as a result of government policy to provide each county with at least one public asylum, as legislated in the County Asylum Act of 1808. Large sums of money were made available for the asylum building program, of which the Victorians were very proud. Considerable effort went into the design of the buildings, with particular attention to the circulation of air throughout the asylum and to the external decoration.

Asylums were usually sited some miles outside of towns or cities: far enough away to avoid disturbing the public, but near enough to facilitate the transport of patients. Friern Hospital was constructed on a rural site north of London and the nearest railway line was extended to make it accessible. The hospital was opened in 1851 by Prince Albert, the husband of Queen Victoria, and was designed to house a thousand patients. It rapidly filled up and its population continued to grow way beyond the original limit, reaching a peak of 2400 a century after its inauguration. This rapid expansion was a general feature of asylums. Once a place of containment became available, the opportunity was seized to expel from society people with a wide variety of problems who were seen as undesirable. These included people with developmental disabilities, who were sometimes sent to segregated institutions and sometimes mixed indiscriminately with the mentally ill. There were even instances of women bearing illegitimate children who, when pregnant, were sent to such institutions where they spent the rest of their life.

As their populations grew steadily, the asylums became increasingly overcrowded, until they reached the point where the beds were so close together that patients had to climb over others' beds to reach their own. Overcrowding generated squalor, and since the staff were unable to cope with the large number of disturbed patients, it was almost inevitable that abuses occurred. The public scandals that ensued hastened the demise of the asylums, but before charting their decline it is worth considering how they functioned in their heyday.

The typical asylum was either a very large building or a collection of villas set in extensive grounds, which were surrounded by a high wall with a single entrance guarded by a gate lodge. Within the walls were vegetable gardens and often a farm with cows and sometimes pigs. Some asylums had their own artesian wells and many were virtually self-sufficient or even produced a surplus. Powick hospital in the west of England during the 1920s was selling one thousand bushels of wheat and 1800 pounds of beef per year. The patients provided the labor to work the farms, as well as helping in the hospital kitchens and the laundry. The use of unpaid patient labor was viewed by the trade unions in the West as exploitation and it ceased in most hospitals in the mid-twentieth century.

When patient labor was replaced by a paid professional workforce, activities for the patients had to be organized. These took the form of recreational activities, designated as occupational therapy, and work-like activities, often termed industrial

therapy. Industrial therapy ranged from simple repetitive tasks such as assembling darts to complex procedures such as making furniture designed by the staff. The industrial therapy unit at Friern Hospital, at its peak, employed 120 people, some of whom commuted daily from their homes since nothing comparable existed in the community.

The Turning Point

In the UK, the number of psychiatric beds climbed steadily for more than a century, reached a peak of 149 000 in 1954, and since then has fallen progressively. A similar pattern occurred in the USA, where the number of residents in state psychiatric hospitals declined from 186 per 100 000 in 1969 to 33 per 100 000 in 1992. Psychiatric bed occupancy has also been falling in most Western European countries since the 1970s but the rate differs by country. In Italy the number of psychiatric hospital beds rose from 36 000 at the beginning of the century to a peak of 188 000 in 1971. Since then there has been a steady decline to 7500 in 1999, including both state and private hospitals. In Israel the number of psychiatric hospital beds has fallen from more than 11 000 to 6000 in 1999. Four factors can be identified that prompted this change: the introduction of specific antipsychotic drugs, abuse of patients by staff that provoked public scandals, critiques of institutions by sociologists and others, and a change in the attitudes of psychiatrists.

It has been claimed that the key factor was the advent of antipsychotic drugs, but that cannot be the only answer since chlorpromazine, the first of the genre, came into general use in 1955, whereas in some pioneering psychiatric hospitals in the USA and UK the bed numbers began to fall in the late 1940s. By controlling disturbed and unacceptable behavior, the drugs certainly facilitated the process of deinstitution-alization, but they did not initiate it. Similarly, public scandals gave a high profile to the problems of institutions and helped to mobilize a search for alternative forms of care, but did not start the process.

Academic books criticizing psychiatric institutions began to appear at the end of the 1950s and certainly exerted some influence on the attitudes of psychiatrists and other staff. The first was by a psychiatrist, Russell Barton, and appeared under the title *Institutional Neurosis* in 1959. The term he invented was inappropriate since the great majority of patients adversely affected by institutional living suffered from psychotic illnesses. However he accurately described the apathy, inertia, lack of motivation and affective poverty which characterised long-stay patients in institutions. This was followed by a particularly influential book by Erving Goffman (1961) entitled *Asylums*. Goffman spent a year in the late 1950s observing interactions in a US psychiatric hospital. He described the humiliating rituals which were inflicted on new entrants and saw their main purpose as being to sever all links with the everyday world outside the institution. He coined the term 'total institution,' which he defined as 'a place of residence and work where a large number of like-situated individuals, cut off from the wider society for an appreciable period of time, together lead an enforced, formally administered round of life.' Asylums certainly provided accommodation and work, but in addition many supplied every amenity likely to be required in everyday life, including a place of worship, a patients' club, hairdressers, and shops, so that there was no need ever to leave the confines of the hospital.

These books, however seminal, appeared in print too late to explain the fall in beds in the pioneering asylums. For example, Dr. Duncan Macmillan, who occupied the unique position of Medical Officer for Mental Health for Nottingham, UK, established an outpatient clinic in the local general hospital in 1932. Later he became Physician Superintendent of the psychiatric hospital, Mapperley, and by 1957 the senior members of the hospital's medical staff were spending over 50 percent of their time in 34 clinics in the community. As a consequence of these developments, the number of inpatient beds began to fall in 1949.

World War II seems to have provided psychiatrists with experiences that led to innovative experiments in therapy. This entailed the recognition ofthe legitimacy of fear in the face of appalling danger, and affected soldiers were treated with psychological approaches. Military psychiatrists saw healthy young men break down with severe psychiatric syndromes under stress, and then recover when treated in group settings. In these military centers every aspect of the regime was designed to counteract the development of chronicity. At the end of the war, the army psychiatrists, imbued with optimism about the potential for recovery, took up posts in the psychiatric hospitals. They included British pioneers such as Maxwell Jones (1952) who founded the Henderson hospital as a therapeutic community for people with psychopathy, and Tom Main, who took over and transformed the Cassell hospital. As directors of psychiatric hospitals, these charismatic men had the power to make their vision a reality, unimpeded by bureaucratic inertia. However, they had to fight the resistance of other members of staff, who were often more institutionalized than the patients.

In the USA the impetus for attitude change also arose from the war, but from a surprisingly different source. Conscientious objectors were obliged to do public service in psychiatric hospitals. They brought into these institutions a humanitarian attitude which had not been dulled by the hospital regime. Furthermore, as they had no professional training, they treated the patients as equals and as valued individuals. The ferment they introduced into the system worked its effects on the professional staff.

Decline and Fall of the Psychiatric Hospital

Once the antipsychotic drug, chlorpromazine, became available, the handful of pioneering hospitals were joined by the rest in discharging patients in large numbers, and a steady decline in the number of occupied beds occurred in the USA and in England and Wales. This was not observed in Scotland, which had a separate health administration. The decline in England and Wales was so steady over a number of years that Tooth and Brooke (1961) predicted that the existing long-stay population of psychiatric hospitals would be eliminated through discharges and deaths by the year 1986. The reasons their prediction proved to be wrong are of considerable import.

First, some patients admitted to acute wards remained in hospital for over a year. They were termed the 'new long-stay' in distinction to the old long-stay who were a relic of custodial care. Of course the distinction between the two is arbitrary depending on the point in time when observations are made. The significance of this group is that their problems are clearly not created by the institution but are a consequence of their psychiatric illness. Hence closure of the institutions will not abolish the 'new long-stay.' The second group of patients that confounded Tooth and Brooke's prediction are those whose behavior is so disturbed and disturbing that they cannot be moved to homes in the community. These 'difficult-to-place' patients pose a major challenge to deinstitutionalization and will be considered in more detail later.

Despite these problems, the run-down of the asylums has progressed to the point where many of them have been closed. In the USA the number of state psychiatric hospitals decreased from 277 in 1970 to 231 in 1996. There has been an even more dramatic change in England and Wales where 100 of the 130 psychiatric hospitals have closed since 1980. In Italy the closure of the institutions was achieved by revolution rather than evolution. In 1978 the Italian parliament passed Law 180 which prohibited the admission of patients to psychiatric hospitals thenceforth. This legal constraint on admissions did not directly affect the patients already resident in the asylums, and it took many years to improve their conditions of life.

Law 180 reminds us that changes in psychiatric services cannot be carried through by staff alone. They require the backing of the government of the day to provide the financial resources necessary to create and develop new services. The Italian law was pushed through parliament by the Communist party, whose support was recruited by Franco Basaglia, a charismatic psychiatrist and founder of the Democratic Psychiatry movement. In the UK there was no political polarization over deinstitutionalization. The closure of psychiatric hospitals was heralded by the Conservative Minister of Health, Enoch Powell, in a famous speech in 1961 in which he referred to the asylums as 'isolated, majestic, imperious, brooded over by the gigantic watertower and chimney combined, rising unmistakeable and daunting out of the countryside.' Successive governments, whether of the right or the left, continued to endorse the policy, but with different agendas: the left supported patients' rights for ideological reasons, while the right hoped to save money by closing the old asylums.

Alternatives to the Psychiatric Hospital

Where were patients to live when they were discharged from an asylum? Wherever the process of discharge has been studied it has emerged that the least disabled patients were selected to move out first. Many of these patients were able to cope in independent accommodation. As the more dependent patients were considered for discharge, it became evident that they needed supervision in their community homes. For the most disabled patients, 24-hour supervision was required. The closure process for two London psychiatric hospitals, Friern and Claybury, was studied by the Team for the Assessment of Psychiatric Services (TAPS) over 13 years (Leff 1997). TAPS found that 78 percent of the long-stay patients were discharged to staffed homes. In the USA, Eileen Rothbard and her colleagues (1999) monitored the closing of Philadelphia State Hospital and found that 75 percent of the long-stay population were living in residences with 24-hour staff supervision. Intensive staffing invariably carries a high cost, since over 80 percent of the cost of care in the community is contributed by staff salaries.

The obvious choice might seem to be to resettle patients with their families, but this is rarely achieved for the long-stay patients. In the Friern and Claybury programs only 4 percent of them returned to their family home. This is partly due to loss of contact with relatives over the course of decades in an institution, which had occurred to 75 percent of the Friern and Claybury patients. The other reason is that a high proportion of patients are experiencing active delusions and hallucinations which are not controlled by medication and require specialized care.

In many of the resettlement programs, the more disabled patients live in small groups in ordinary houses, indistinguishable from neighboring buildings. This has an obvious advantage in easing reintegration into the community. However there are barriers other than distinctive architecture, which became apparent from the TAPS evaluation. Nearly 700 long-stay patients were followed up for five years after discharge to homes in the community. Although there was no amelioration of their psychiatric symptoms or problems in social behavior, they did acquire skills in caring for their homes and in using community amenities. Compared to the hospital wards, they enjoyed much greater freedom in their homes, which they greatly appreciated. When asked where they wanted to live, 84 percent preferred to stay in their current home, and almost all those who wanted to move wished to live independently. Only a handful desired to return to the hospital.

Beneficial outcomes for long-stay patients discharged from psychiatric institutions have been reported by other researchers in the UK and the USA, although few have studied a large sample of patients over a long period of time. An exception is Courtney Harding and her colleagues (1987) who conducted a 32-year follow-up of 269 patients discharged from Vermont State Hospital, USA in the 1950s as part of an experimental rehabilitation program. The findings were that over half the patients were functioning much better than expected.

One drawback to life outside the asylum that TAPS revealed was the failure of most patients to develop social relationships with their neighbors. Undoubtedly the impairment of social skills by schizophrenia was contributory, but it is not the whole story. Most of the patients were resettled in cities, where there is not a strong sense of community and even healthy neighbors have little to do with each other. Geoffrey Wolff and his colleagues (1996) mounted an experimental study of an education campaign in a street in which long-stay patients from a south London asylum were resettled. The campaign was successful in reducing neighbors' fear of the mentally ill and in increasing their social contact with the new residents.

Another problem is the lack of employment prospects for people with a long history of psychiatric hospitalization. When the national unemployment rate is high, it is almost impossible for someone with such a history to obtain a job. One solution is to establish cooperatives, or 'social firms' as they are sometimes known. These are particularly well-developed in Italy, and a comparison of people with schizophrenia between

Boulder, Colorado, and Bologna, Italy (Warner et al.1998) showed that the Italian patients worked for more hours and earned more than the US patients. The development of employment opportunities for mentally ill people in the community needs far more attention than it has received to date, as it is one of the prime means of social integration.

Is Community Care Affordable?

It is not difficult to provide cheap community care. There have been several low-cost schemes to house discharged patients in the USA and the UK. In the USA, 'board and care' was an inexpensive way to provide patients with accommodation, but very little else. The proprietors of these homes ran them as commercial enterprises and had little or no instruction in the care of the patients. It is hardly surprising that patients were treated extremely badly in some cases, giving rise to public scandals. In the UK, patients were placed in seaside boarding houses, many of which are empty during the winter and would otherwise have closed until the summer season. Hence the offer of permanent residents all the year round was attractive to their owners. However, no provision was made for the patients' work and leisure needs, and television documentaries showed pathetic scenes of patients wandering along deserted wind-swept promenades in the driving rain. Patients placed in these seaside towns were even further from their districts of origin than when in the asylums.

The crucial question is how a *good* system of community care compares with hospital care in terms of cost. There have been very few attempts to make this comparison. The TAPS project involved a collaboration with a team of health economists who carried out a detailed costing of all services used by the long-stay patients when in Friern and Claybury hospitals and then when they had been in the community for one and five years. As this was done prospectively, the costs for specific individuals can be compared over time, adjusting for inflation. For all the discharged patients, the cost in the community after the first year was slightly less than their cost when in hospital, although the community costs rose slightly by five years (Leff 1997). However, not all the long-stay patients were discharged to community homes. A sizeable group were considered to be too disturbed to move to the community. When the hospital closed these difficult-to-place patients were transferred to highly staffed facilities, mostly on other hospital sites. The high staffing levels made their care very expensive, so that when they were added into the cost equation, community care became more expensive than care in the hospital had been.

By contrast, a costing exercise by Eileen Rothbard and her group (1999) for patients discharged from Philadelphia State Hospital showed that community care was considerably cheaper than the estimated cost of hospital care. Cost comparisons on their own are insufficient: what is needed are cost-benefit analyses across sites and countries.

Critiques of Deinstitutionalization

Criticisms have come from within the psychiatric profession and from outside, mainly from the media, from disgruntled family members, and from citizens who object to sheltered homes being established in their neighborhood. One of the most stringent professional critics has been Harold Lamb (1976) in the USA who has pointed to the large number of severely mentally ill people who are in prison. He argues that patients have been transferred from a relatively benign institution, the psychiatric hospital, to a punitive one, prison, and has dubbed this process 'transinsti-tutionalization.' Two related issues are raised by his critique: does community care inevitably lead to the imprisonment of the mentally ill, and are the mentally ill more dangerous than the average citizen? In the TAPS study, of the 670 patients followed up for five years after discharge only five spent time in prison, while 13 (2 percent) committed assaults on others. In the study by Eileen Rothbard and colleagues (1999), 2 percent of the 321 long-stay patients followed up for three years were involved in the criminal justice system. Thus it appears that a well-organized and funded community program does not lose many patients to prison, and furthermore that the great majority of mentally ill people are not dangerous. Unfortunately the media prefer to highlight the few tragic homicides that do occur, hence reinforcing the public stereotype of the 'mad axeman.' It is this irrational fear that fuels the 'not in my backyard' attitude of some members of the public. Geoffrey Wolff and his colleagues (1996) have shown that a localized educational campaign can reassure neighbors about ex-hospital patients coming to live in their street.

The other concern of the media and the public is that many patients discharged from long-term care end up on the streets. While the number of homeless mentally ill has undoubtedly increased, several surveys have found that very few of them have spent much time in psychiatric institutions. In support of this observation, less than 1 percent of the TAPS sample became homeless over five years and only 2 percent of the Philadelphia State Hospital ex-patients over three years. While no mentally ill person should be without a home, the problem stems from the inadequacy of aftercare for those coming out of admission units and not from the long-stay patients who are resettled in sheltered residences.

This raises the question of the balance of resources to be invested in community care programs. The asylums represent a large investment of capital, in the land and buildings, and of revenue, in staff salaries. The value of the site is often considerable since urban expansion has incorporated the once distant asylums. Various financial strategies have been used to release the capital and revenue bound up in the asylum, so that they can be reinvested in providing a good quality service for the long-stay patients. But patients with long-term disabilities continue to arise in a population and need the kind of rehabilitation facilities which used to exist in the psychiatric hospitals but have generally not been re-provided in the new services. Additionally, the care of acutely ill patients is becoming increasingly difficult with the ready availability of street drugs. It seems to be difficult for funders to invest in acute and rehabilitation services at the same time as providing for the long-stay patients coming out of the institutions. Within North America and Europe, only Finland seems to have achieved a reasonable balance between these two sectors. Without such a balance, it is not surprising that family members are discontented with the service offered to their acutely ill

relatives, and that deinstitutionalization has become the target of criticisms that should justly be directed at the failure to provide a *comprehensive* psychiatric service of a uniformly high standard.

Abstract

Deictic signs symbolically denote some aspect or component of the *speech situation* – the extra-linguistic context in which they are used, such as the speaker, time, or place of an utterance. Although they are symbolic as types, their tokens in specific contexts represent the particular component of the speech situation indexically. The semiotic nature of this kind of reference, its exact communicative prerequisites and functions, its acquisition by children, and its processing have long puzzled scholars throughout the cognitive sciences. This article presents an overview of deictic signs and introduces some major research themes.

Introduction

The term *deixis* was introduced by the German linguistic and psychologist Karl Bühler (1879–1963) in his 1934 magnum opus *Sprachtheory* ('theory of language,' or 'linguistic theory'). It refers to the central phenomenon that Bühler dedicated his book to the fact that when we speak (or sign, in the sense of using sign language), our utterances are peppered with expressions/signs that refer to components of the *speech situation* – the extralinguistic (i.e., real-world) context of the utterance. Take, for example, the utterance *She brought this flower for me yesterday*. The pronoun *me* refers to the speaker. It has a different meaning depending on who utters it. This is an instance of 'person deixis.' The demonstrative *this* selects a referent in the interlocutors' proximity – *this flower*, as opposed to *that* one over *there* (at least in its most simple spatial use, exemplifying 'spatial deixis'). The verb *bring* designates transport to a deictically defined location (*here*); this could be the location at which the conversation takes place, or the speaker's home (there are in fact many possibilities). This illustrates another subtype of spatial deixis – 'place deixis.' The past tense of *brought* indicates that the flower arrived at this location prior to the time of utterance, and the adverb *yesterday* restricts this time interval to the day before the day of utterance. Both instantiate 'temporal deixis.' So, in order to know what exactly is meant by *She brought this flower for me yesterday*, and whether this statement is true, one first needs to know who uttered it, on what day, and where. No language has been attested to have a genuine event deictic, but many languages (e.g., Yucatec Maya) have manner indexicals (translating 'like this/that') that are used in reference to events. Further possible types of deictic expressions are discussed in the Section 'Deictoids: Honorifics, Projective Spatial Relators, and Modals.'

Deixis derives from the Greek verb *δείκνυμι* 'show,' 'point,' a metaphor Bühler uses to refer to the fact that deictic signs receive their *referent* – the particular component of the speech situation they refer to – via a relation of spatial and temporal contiguity between the utterance and the speech situations. In this capacity, Bühler likens them to pointing gestures, which often accompany the use of *deictics* – hence the metaphor. Nearly 70 years before Bühler, the American philosopher Charles S. Pierce (pronounced like *purse*) – now often considered one of the most original thinkers of the Modern Age – proposed a classification of signs with roots in medieval philosophy. Peirce treats as signs anything that can be used as a representation of something else – not only linguistic expressions and diagrams, but also cognitive representations or thoughts. Peirce (1867) classified signs based on the relationship between their form and the referent into *icons* (constituted by similarity; e.g., portraits, blueprints, and maps), *indices* (singular *index*; constituted by a causal relation or one of spatiotemporal contiguity; e.g., footprints as a sign of the person or animal who left them), and *symbols* (constituted by convention; e.g., hammer and sickle as the symbol of Communism).

Index of course invokes the same metaphor as *deixis*. However deictic signs are not primarily indices but rather symbols – as are, arguably, all linguistic signs. To see this, consider the fact that the meaning conveyed by the deictic pronoun *I* in English is expressed by *moi* in French, *yo* in Spanish, and *tèen* in Yucatec Maya. Obviously, the combination of the particular string of sounds (or the letters that stand for them in written speech) and this meaning is conventional, in the sense that for any individual speaker, the particular string is associated with this meaning only because they have learned this association from their peers. However, there is a secondary indexical association between the referent of the sign in a given context and, not the sign as an abstract object of the speaker's knowledge and practice, the 'type' in Peirce's terms, but rather the particular instance of the sign used in the particular context – the particular 'token' of the sign, as Peirce puts it. For example, with every 'turn' in a conversation the word *I* refers to a different speaker, identified by the indexical relation between the utterance (and thus the tokens of *I* contained in it) and the person producing it. So deictic signs are symbols as types, but their tokens in any particular utterance bear an indexical relation to their referents (cf also Silverstein, 1976; Tanz, 1980; inter alia).

Linguistic meaning is studied by a number of subdisciplines of linguistics and neighboring sciences, including notably semantics, pragmatics, and linguistic anthropology. Semantics is primarily concerned with the study of the meanings of (simple and complex) linguistic signs, whereas pragmatics is the study and theory of utterance meanings. (Utterances in

a narrow sense may be understood as actions of language use with recognizable communicative intentions.) Linguistic anthropology in turn is dedicated to the study of cultural practices of language use. Because deictic signs are a manifestation of the context-dependence of linguistic meaning sui generis, deixis has received more attention among students of pragmatics (e.g., Levinson, 1983, 2004) and linguistic anthropology (e.g., Levinson, 2004; Silverstein, 1976) than among semanticists (e.g., Schlenker, 2003). Deixis has also been studied extensively elsewhere in the cognitive sciences, notably by philosophers of language (e.g., Barwise and Perry, 1983; Braun, 2012; Kaplan, 1989) and developmental psychologists (e.g., Piaget and Inhelder, 1956; Tanz, 1980).

Deixis, Indexicality, and Context Dependence

While the term 'deixis' has become customary among linguists and psychologists, philosophers of language such as Kaplan (1989) often prefer the Peirce-inspired *indexicality* (alongside *indexicals* for deictics) with roughly the same meaning. This can cause confusion, as token indexicality in Peirce's sense is not restricted to deictics, but characterizes a considerably larger class of linguistic signs.

It is one of the fundamental design features of human language that the interpretation of linguistic utterances may strongly depend both on the linguistic and the nonlinguistic context. It has been argued by philosophers that in fact without some such underlying indexicality in all referring expressions, no successful reference to the world would be possible (Putnam, 1975). Take again the example *She brought this flower for me yesterday*. The noun *flower* has a meaning that can be defined independently of context (e.g., 'the reproductive organs of a plant and their colored (nongreen) envelope'), and it can be used to refer to real or imaginary flowers that fulfill this definition. Yet, in order to refer successfully to a plant as a *flower*, more than mere knowledge of the meaning of *flower* is required: speaker and addressee have to agree on the plant being identifiable by that term. And the conditions on this agreement may in fact vary with context. For instance, if one of the interlocutors is a botanist, they might use the term *flower* differently, not requiring the envelope to be colored.

However, there are expressions whose very meaning inherently refers to the context. Such expressions cannot be used to refer to anything before the relevant information is retrieved from the context. Deictics instantiate this class of expressions – but they do not exhaust it. In the above example, the pronoun *she* takes up a referent of the feminine gender that must have been introduced in the preceding stretch of discourse. If the speaker announced in the preceding utterance that he or she is planning to marry his/her girlfriend Sally, then it will be inferred that it was Sally who brought him/her the flowers. This illustrates *anaphoric* reference. In contrast, *deictic* reference occurs whenever a linguistic sign receives part of its meaning from the extra-linguistic context.

Anaphoric expressions generally admit deictic use, while anaphoric use of inherently deictic terms is usually more restricted (but see Section 'The Semantics of Deixis'). The English demonstratives *this* and *that* can both be used anaphorically, though under slightly different conditions (see Fillmore, 1997), and so can the proximal and distal place adverbs *here* and *there*. In contrast, in Yucatec Maya, only the distal demonstrative forms and adverbs can be used anaphorically (Bohnemeyer, 2012b; Hanks, 1990). The combined impact of the rather weak deictic anchoring of demonstratives in some languages and the pervasiveness of their nonspatial uses has led some researchers to propose nonspatial analyses of the underlying meanings. Similarly, Wilkins and Hill (1995) show that *go* and its equivalents in other languages only acquire a deictic reading pragmatically, through the contrast with a truly deictic *come*.

Another class of indexicals are so-called *definite descriptions* – phrases formed with a definite article; in English, with *the*. For instance, *the chair* refers to a chair that the speaker assumes to be uniquely identifiable to the addressee, perhaps because it has been mentioned before or because there is only one in the room, and so on. Therefore, definite descriptions can be used deictically provided the uniqueness condition is fulfilled in the context: *Move the chair over!* will be felicitous in a situation in which there is only one free chair in the room and the addressee is aware of that. This kind of use extends to other semantically definite expressions as well, such as determinative adnominal possessive constructions (*Floyd's/ my chair*).

It can be argued that reference to any particulars (people, animals, objects, events, places, and times) that lack a proper name requires some form of deictic anchoring. To understand this claim, one may by way of a thought experiment select an object from the environment at random and try to make a statement about it that avoids any form of deixis. If the claim is correct, it follows that language could not be used to talk about the real world (other than in generic statements) without deictic reference.

Between Deictic and Anaphoric Reference: Transposed Deixis and Text Deixis

'Textual' deixis occurs when (part of) an utterance or discourse is itself the referent of a deictic expression, as in *The preceding sentence contains 27 words*. It has been suggested that some form of textual deixis is present in every anaphoric reference, to the extent that anaphors direct the addressee's attention to an earlier mention of the referent. As long as it is clearly discernible as deixis, textual deixis will always have a *metalinguistic* reference. But as soon as any part of the *meaning* of an utterance becomes the target, textual deixis becomes increasingly indistinguishable from anaphoric reference (Levinson, 2004). An intermediate case is constituted by reference to propositions, facts, and events (cf Lyons, 1977).

'Transposed' deixis is constituted by an *imagined* situation replacing the actual utterance context as the 'indexical ground' of a deictic form. When the imagined situation is itself described in discourse, this may have a quasi-anaphoric effect. Consider *He arrived in Paris in early May. Now he finally had the time to explore this great city*. The deictic forms in the second sentence refer to the time and place introduced in the first sentence. However, they are relativized to the character perspective and therefore function as true deictics. This perspectivizing effect was actually one of the primary

concerns of Bühler (1934) (cf also Section 'Introduction; Deictoids: Honorifics, Projective Spatial Relators, and Modals').

Deictoids: Honorifics, Projective Spatial Relators, and Modals

I would like to propose *deictoids* as a cover term for several classes of indexical expressions that are commonly considered deictic because their use is dependent on properties of the extra-linguistic context, but which differ from the prototypical instances of person, spatial, and temporal deictics discussed so far in that the latter, but not the former, semantically denote variables the value of which is either a constituent of the speech situation or, as in the cases of tenses and demonstratives, is defined via a relation to a constituent of the speech situation.

For instance, '*I*' denotes the speaker of the utterance, whoever that may be in any given instance. '*Now*' denotes the time of the utterance, whenever that may be in any given instance. '*This*' denotes an object located near '*here*,' the 'deictic center' (Bühler, 1934), the place occupied by one or all of the interlocutors. And (deictic or 'absolute') tenses denote times in the present, past, or future of utterance times. This is not really the case with *honorifics*. In popular usage, the prototypical 'honorifics' are titles, such as *Ms. (Brown)* or *Her Royal Highness*. But in scientific usage, 'honorifics' encompasses any and all semantic expressions of the social relations between the participants of the speech act the utterance is involved in carrying out – the speaker, addressee, some person referred to, and/or bystanders of the interaction, usually as a means of expressing respect or deference for or solidarity with them. For example, most European languages contrast two addressee pronouns, one that is exchanged among speakers who are both 'solidaries' (friends, relations, or members of the same 'in-group') and status equals, the other taking over when one or both of these relations are absent, with the precise conditions varying from language to language and being subject to change over time (Brown and Gilman, 1960). Other languages (a particularly well-known case is Japanese; e.g., Shibatani, 1990: pp. 374–379) have more complex systems that go beyond binary contrasts and beyond the speaker–addressee relation. In addition, apparently all languages have expressions that do not directly express social relations among the interlocutors, but whose use nevertheless implies them, including a plethora of strategies to convey various forms of politeness (Brown and Levinson, 1987).

All of these expressions are context-sensitive, since their use reflects the speaker's construal, for the purposes of the particular utterance, of the social relations among the interlocutors. By the same token, such expressions are indexicals, and in fact resemble deictics, in that it is specifically the extralinguistic context that they are sensitive to. Fillmore (1997[1975]) in one of the classic texts on deixis, in fact, proposed to treat these under the new category of *social deixis*. However, for, say, an honorific to have a semantics akin to those of prototypical deictic expressions, it would have to encode the relation between – say – the speaker and addressee as a variable, the value of which is picked up from the speech situation. Consequently, one and the same such hypothetical honorific might express deference in one context and solidarity in another. Such honorifics are unattested. Instead of retrieving social relations as values of a variable, honorifics actually classify them. For a recent treatment of the semantics of honorifics and other expressions of 'social deixis,' see Potts (2005).

Bühler (1934: p. 129) noticed that spatial relators such as 'left,' 'right,' 'front,' and 'back' are systematically ambiguous between two types of interpretations, implying different perspectives or, in terms of the more recent literature, 'frames of reference' (Friederici and Levelt, 1990). Thus, *The rock is left of the tree* means that the rock is to the left of the tree as projected from an observer, as the tree has no inherent left, and *The rock is in front of the tree* means it is between the observer and the tree, as the tree has no inherent front. This perspective may be understood as that of the speaker, the addressee, both, or as that of some generic observer. In contrast, when used with respect to people (which do have an inherent left side) or, for instance, buildings (which do have an inherent front), such terms may, but need not, imply the perspective of an observer external to the person/building. In the psychological literature, the former use is known as 'egocentric' and the latter as 'allocentric.' Bühler treated the egocentric, but not the allocentric use as deictic. However, Bohnemeyer (2012a) argues that both types of uses – and in fact all 'projective' (Piaget and Inhelder, 1956) spatial relations, that is, relations depending on reference frames – are indexical, in that the reference frame is always based on one or more axes from some entity or environmental gradient which the interlocutors need to identify in the speech situation. For instance, in order for a 'geocentric' description such as *The rock is upriver of the tree* to be interpretable in a given context, that context must contain a salient river from the course of which the reference frame can be projected.

But while projective spatial relators are thus arguably indexical, and in fact depend on the extralinguistic rather than the linguistic context for their interpretation, they are nevertheless deictoids rather than deictics. This is because they do not actually denote the contextual axes involved in their interpretation. Instead, they denote vectors and spatial regions defined with respect to these axes.

Yet another example of this type of dependence on the extralinguistic context may be found in modal expressions. Consider, for example, the various possible interpretations of '*may*' in *Gusty winds may exist* (an example courtesy of Douglas Adams' unfinished novel *The Salmon of Doubt*) – say, nomological possibility relative to the laws of physics, epistemic possibility relative to the knowledge of the speaker, and meteorological possibility relative to the weather phenomena that have been observed over time in a given location. The third interpretation was presumably the one intended by the New Mexico Department of Transportation, who put this message on a common road sign. This last type is an example of what Kratzer (1981), in a classic theory of the semantics of modal expressions, calls 'circumstantial modality.' According to Kratzer's theory, all of these different uses of *may* share the semantic feature of existential quantification over possible worlds ('There is at least one possible world in which *p* is the case,' where *p* is the proposition inside the scope of the modal operator – in the

example at hand, the proposition 'Gusty winds exist'). Possible worlds are possible contexts or situations relevant to the evaluation of the meaning and truth of propositions. Where they differ is what Kratzer calls the 'modal base,' which spells out the set of possible worlds relevant to the evaluation of a given modal operator – the set of all worlds consistent with the laws of physics; the set of all worlds consistent with the speaker's knowledge; and so on. And the modal base is part of the 'conversational background,' and thus the extralinguistic utterance context. And since the modal base is once again not actually denoted by the modal operator, but merely involved in its interpretation, the modal operator is a deictoid rather than a deictic.

Lastly, even if modals such as *may* are deictoids, this is not to deny the possible existence of truly deictic expressions which in a broad sense may also be considered 'modal.' Prime candidates are moods – grammatical categories that express the distinction between reality and irreality – and also semantically related adverbs such as *actually*. For instance, Kaplan (1989) (see Section 'The Semantics of Deixis') argues that *actually* refers to the utterance world – a possible world that contains the utterance, that is, the 'real world' of the utterance – in a manner straightforward enough to possibly qualify as a genuine deictic.

The Semantics of Deixis

Indexical elements have, arguably, three functions in linguistic utterances. First, they represent the referent in the utterance as a variable. Second, they specify what may be called a *search domain* for the referent in the context (the linguistic context for anaphoric and text-deictic expressions and the extralinguistic context for other deictic expressions). For instance, in the case of the place deictics (*here*, *there*) and demonstratives (*this*, *that*) of English, these search domains are complementary areas of proximity to and the distance from the speaker's and/or addressee's location, at least as far as concrete, literal spatial uses of these expressions are concerned. And third, they direct the addressee's *attention* to the referent (Diessel, 2006).

The search domain can be thought of as a property (formally, a predicate) that possible referents must instantiate. This property is specified as part of the semantics of the indexical. In this respect, it resembles the conventional type meaning of non-indexical expressions, which can be conceived of as a knowledge structure that allows speakers to determine whether and to what extent a given individual or state of affairs (etc.) can be referred to using the term, that is, belongs to its 'extension,' its set of possible referents. This knowledge structure is the 'sense' of the term in Frege's (1892) classic formulation, formalized by the 'intension' in Carnap (1947), a function that assigns to every possible world (see Section 'Deictoids: Honorifics, Projective Spatial Relators, and Modals') the extension of the term in this world. Carnap's intension describes mathematically what Frege's sense does cognitively, allowing us to identify the possible referents of the term in every possible context or 'world.' For example, assuming the sense of *flower* can be paraphrased as 'the reproductive organs of a plant and their colored (nongreen) envelope,' this gives speakers a set of criteria they can rely on to determine whether a given situation contains any possible referents of *flower*.

However, in other respects, the conventional type meaning of indexicals is fundamentally different from the sense or intension of non-indexical expressions. To begin with, the search domain is defined with respect to the utterance, as a property of its context. Hence, the indexicality is irreducible. It is impossible, for example, to paraphrase the meaning of indexicals in strictly non-indexical terms. One might try to paraphrase *I am writing this article* as "The person who writes the sentence that contains the reference to the person at the time of writing the sentence is writing an article that contains the sentence." This in fact eliminates all deictic reference, but it also fails to identify any article or person in particular and, therefore, makes little sense.

Moreover, while an expression such as *flower* can be said to have an extension or set of possible referents that varies with the situations or possible worlds talked *about*, deictic expressions refer to particular individuals, times, or places that vary, not with the situation talked about, but with the utterance itself and specifically its extralinguistic context. For illustration, consider a sentence such as *The flowers were in bloom every time you and I met*. *The flowers* might refer to a different set of flowers with each meeting (perhaps the meetings took place in different years and in different places). But the referents of *you* and *I* clearly cannot vary in this way. Indexicals are generally considered what Kripke (1980) calls 'rigid designators' – expressions associated with a fixed referent across possible worlds.

Kaplan (1989) proposes a two-tier theory of linguistic meaning. One tier is constituted by what Kaplan calls 'content.' Contents map pairs of (extralinguistic) contexts and possible worlds into extensions, thus fulfilling the role of Carnapian intensions. The other tier is a mapping from possible contexts into contents. This is the 'character' of the expression. Non-deictic expressions – especially predicates, which formal semanticists generally assume to represent the meanings of most content words – have contents that do not vary with context, but assign variable extensions to different possible worlds. In this sense, their character is invariable, but their content is variable. Conversely, deictic expressions have different contents in different contexts – for example, the speaker of the utterance in the case of first person pronouns – but then map this same content into all possible worlds. Thus, their character is variable, whereas their content is not. Kaplan's theory is perhaps the most prominent out of an entire line of dual-track approaches to the semantics of indexicals (see Levinson (2004) and Braun (2012) for further discussion).

An interesting prediction Kaplan derives from his theory that has attracted much attention in recent years is that the referent of deictic expressions should not ever be sensitive to the linguistic context in which the expression appears. For example, while the pronoun *I* will be understood to refer to Sally in (1), where the object of *say* is Sally's directly (i.e., verbatim) quoted utterance, it can only refer to the speaker of the matrix utterance in (2), which cannot be Sally (unless she is attempting to conceal her identity or suffering from split-personality disorder):

1. Sally said 'I am right!'
2. Sally said that I was right.

Numerous apparent violations of Kaplan's generalization (often referred to as the 'Monster Prohibition,' after Kaplan's term for hypothetical deictics whose reference is shifted by their linguistic context – 'monsters') have been cited (see e.g., Schlenker (2003) for an overview and discussion). For example, many languages have so-called 'logophoric' pronouns, which are used specifically to represent the quoted speaker in indirect speech (i.e., in place of *I* in contexts such as (2)). Purely logophoric pronouns are a species of anaphoric, rather than deictic, expressions. But some languages allow or require logophoric *uses* of otherwise deictic first and second person pronouns; an example discussed at length in Schlenker's (2003) work is Amharic (Semitic; Ethiopia). Munro et al. (2012) discuss the case of Matsés (Panoan; Peru, and Brazil), where *all* deictics are systematically shifted to the perspective of the quoted speaker in what based on syntactic evidence nevertheless appears to be indirect speech.

The Pragmatics of Deixis

The complexity of deictic search-domain distinctions varies considerably across languages (see Anderson and Keenan, 1985; Levinson, 2004; Weissenborn and Klein, 1982). Where the English demonstratives *this* and *that* make just a two-term distinction of distance relative to the speaker, the Bantu language ChiBemba is said to distinguish proximity to the speaker, proximity to the addressee, proximity to both, distance to both, and relative proximity to the speaker *with respect* to the addressee (other languages have been claimed to make even more fine-grained distinctions, but more recent research has failed to confirm such analyses). Whereas English demonstratives distinguish essentially *relative* distance, such that *this* and *that* may be used *contrastively* within a space close to the speaker, the Yucatec system mentioned earlier operates on an *absolute* proximal–distal distinction (Bohnemeyer, 2012b). Similarly, whereas English tenses merely distinguish past, present, and future with respect to the utterance time, many other languages distinguish, for example, a past of the same day from a 'yesterday' past, a 'tomorrow' future from a more distant future, and so on. ChiBemba distinguishes four such 'degrees of remoteness' in the past and four in the future (Givón, 1972). For an example of a complex pronominal system, see Foley (1997: pp. 112–118) on Tagalog.

The conditions for felicitous deictic reference in space may depend on whether the addressee's attention is already on the referent or not. Some languages even have a formal contrast that matches this distinction. Thus, in Yucatec, the regular demonstrative forms translating 'this' and 'that' are expanded by deictic place adverbs ('this here,' 'that there') when the addressee's attention is not on the referent (Bohnemeyer, 2012b). It has been argued that what is traditionally considered the 'mid-distal' demonstrative of Turkish really has a purely attention-calling function and contrasts with the proximal and distal forms only in this domain, not in terms of distance from the speaker (Özyürek, 1998). Pointing gestures may support attention direction, and in addition serve to narrow down the search domain. Moreover, in case more than one potential referent of the same kind occurs in the search domain selected by the deictic form, pointing gestures may be used to disambiguate the referent. There are, however, search domains that can be referred to without any additional gesture, since they are uniquely identifiable to the addressee. This is true of *here* when used to refer to the speaker's location, and also of *there*, when used to designate the addressee's location, for example, during a phone conversation (Fillmore, 1997). The extent to which the use of spatial deictics requires accompanying gestures seems to vary both with the context of use and with the language-particular term. The attention-directing demonstrative of Turkish cannot be used without a gesture at all. In addition to pointing gestures, iconic and conventional gestures may occur with deictic terms, such as extending the hand, open palm facing up, with presentatives (*Voila!*), or iconically indicating an extension in combination with *this big* or a manner of motion with *like this*. The relationship between such gestures and the linguistic reference act is different from the function of pointing gestures.

Directing the addressee's attention to an object in space is subject to the perceptual accessibility of the object. Many languages exclude the use of certain demonstratives in reference to objects that are not visible, or provide special forms for this purpose. Yucatec has a presentative form for referents of which there is perceptual (e.g., acoustic), but not visual, evidence (Hanks, 1990). In the Wakashan language Kwakwa'la of British Columbia, every noun phrase is marked for whether its referent is visible to the speaker or not (Boas, 1947).

The Genesis of Deixis

It has been argued that pointing gestures are a proto-form of reference, and that accordingly deixis should be the earliest form of verbal reference both in the phylogenetic rise of language in human prehistory (Diessel, 2006; Rolfe, 1989) and ontogenetically in child language acquisition (Clark, 1978; Diessel, 2006). Despite their plausibility, both proposals meet with a major difficulty: the perspectivizing effect of deixis requires highly nontrivial cognitive skills. Thus, there is no conclusive evidence that free-ranging primates use pointing communicatively, and it has been shown that chimpanzees in captivity produce what are commonly considered pointing gestures irrespective of whether they are seen by the addressee or not; in other words, they seem to lack awareness of the interlocutor's mental state of attention (Povinelli et al., 1997). Likewise, it is not the case that the first referring expressions acquired by children are deictics. The first deictic forms acquired by English-learning children are personal pronouns, and the adult-like use of these does not occur before the third year of life. Perspectivizing expressions such as *in front of* are consistently used nondeictically at first, and deictic usage does not come in until the fifth year (cf Piaget and Inhelder, 1956; Tanz, 1980).

Conclusions

Deictic reference plays a particularly important role in language: it serves to glue linguistic representations to the

world, as it were. Deictic expressions directly point the addressee's attention to a referent given in the situation in which the utterance is made, often in combination with gestures. By relativizing the utterance to the particular context in which a particular speaker uses them, they relativize the utterance to this speaker's perspective. The cognitive demands imposed on language processing by this perspectivizing effect are in sharp contrast to the apparent semiotic primitiveness of deictic reference and with its pervasiveness in verbal communication.

Delegation of Power: Agency Theory

Abstract

Delegation is an act where one person or persons relies on other people to take actions on their behalf. It is a critical concept in the study and conduct of politics. Governments use delegation to increase the range of services that they can provide. The most common form of delegation is from lawmakers (e.g., parliaments) to bureaucrats (e.g., cabinet ministries, civil service agencies). Delegation allows government actions to be based on the expertise and abilities of a wide range of people. The downside of delegation, however, is that the people to whom power is delegated can abuse the power they receive. Studies of delegation examine when delegation confers the benefits of expertise to government actors and when it leads to abdication. The theoretical branch of this research is called agency theory. Principal – agent models are mathematical examples of agency theory that provide many studies with logical rigor. Research on delegation is important because it provides people around the world with greater knowledge about how to govern efficiently and effectively. And as nations delegate increasing powers to international organizations such as the European Union and the World Trade Organization, understanding how delegation works is more important than ever.

The Role of Delegation

Delegation occurs when some people ask others to perform tasks on their behalf. For most of us, delegation is an important part of daily life. We delegate to grocers the task of acquiring various foods, we delegate to doctors the task of repairing broken bones, and we delegate to news agencies the task of informing us about local and world events. Delegation is beneficial because we can use it to overcome personal shortcomings. This benefit is important because each of us has limited time, energy, and talents. When the people to whom we delegate devote their time, energy, and talents to our needs, delegation increases the number of tasks that we can accomplish.

In addition to being an important part of daily life, delegation is a central concept in the conduct and the study of politics. Governments great and small use delegation to increase the range of services that they can provide. The governments of large nations, for example, delegate to defense ministries the task of maintaining national security and they delegate to finance ministries the task of managing their nation's economy. Indeed, the modern nation-state could not exist without delegation – for without delegation, lawmakers would be forced to implement and enforce every single law that they pass. With delegation, by contrast, national governments can address a wide range of social issues simultaneously.

In most polities, the most prominent form of delegation is from lawmakers (e.g., parliaments) to government agencies (e.g., economic, security, and public welfare agencies). Such agencies house the persons responsible for enforcing laws and tend to employ the nation's leading experts in the agency's policy area (e.g., economic agencies employ leading economists). In many places, these agencies are known collectively as the bureaucracy. In some places, people who work within these agencies are called bureaucrats or civil servants.

While delegation allows lawmakers to benefit from the expertise and abilities of others, it can also be hazardous. The hazards arise from the fact that delegation entails a transfer of power. For example, every time lawmakers delegate to bureaucrats, they give away a portion of their authority to govern.

The great danger of delegation is that the people to whom power is delegated will abuse the power they receive. This possibility is why some people equate delegation to abdication (e.g., a presidential resignation or a king giving up his throne). If this fear is realized, then those entrusted with the responsibility of governing lose control of what is done in the government's name and anarchy can ensue.

The Study of Delegation

The scholarly study of delegation occurs primarily in the fields of Political Science and Economics. This research examines when delegation confers the benefits of expertise to social decision-makers and when it leads to anarchy. It also helps scholars and practitioners around the world answer one of the most fundamental questions in politics, 'Why do governments do what they do?' For this reason, delegation has been a central focus for social scientists throughout the twentieth century.

Early Studies

In the first half of the twentieth century, scholars sounded a pessimistic tone about the consequences of delegation. Weber's (1946, p. 232) warning is among the best-known:

> Under normal conditions, the power position of a fully developed bureaucracy is always overtowering. The 'political master' finds himself in the position of the 'dilettante' who stands opposite the 'expert,' facing the trained official who stands within the management of administration. This holds whether the 'master' whom the bureaucracy serves is a 'people,' equipped with the weapons of 'legislative initiative,' the 'referendum,' and the right to remove officials, or a parliament, elected on a more aristocratic or more 'democratic' basis and equipped with the right to vote a lack of confidence …

 http://dx.doi.org/10.1016/B978-0-08-097086-8.93029-0

Michels (1915) was also skeptical of delegation. In his iron law of oligarchy, he asserts that democratic organization inevitably becomes subordinated to the interest of their leaders and that the leadership becomes an entrenched oligarchy. Like most of his contemporaries and many of the scholars who followed him, Michels believed in the tendency of people to whom governing power is delegated to use their power against the interests of those who delegated such powers.

Recent Work: The Rise of Agency Theory

Modern scholarship has produced more precise insights about when delegation benefits those who delegate. Many scholars now adopt the language of principal – agent models (i.e., agency theory) to describe the logic of delegation.

The *principal* in principal – agent theories represents someone who delegates. The *agent* represents someone to whom authority is delegated. When a lawmaker delegates authority to an agency, for example, the lawmaker is the *principal* and the agency is the *agent*.

Scholars use principal – agent models to determine when agents do (and do not) act in their principals' interests. *Agency loss* provides a common metric for their distinctions. Agency loss is the difference between the consequences of delegation for the principal and the best possible consequence. Agency loss is zero when the agent takes actions that are entirely consistent with the principal's interests. As the agent's actions diverge from the principal's interests, agency loss increases. When the agent does things that are bad for the principal, agency loss is high.

Research on delegation (see, e.g., Lupia and McCubbins, 1998) shows that agency loss is minimized when two statements are true. The first statement is that the principal and agent *share common interests* (Niskanen, 1971; Romer and Rosenthal, 1978). In other words, the principal and agent desire the same outcomes. The second statement is that the *principal is knowledgeable* about the consequences of the agent's activities. In other words, principals know enough about their agents' actions to determine whether or not these actions serve their interests.

If either of these two statements is false, then agency loss is likely to arise. Agency loss arises when the agent and principal do not have common interests because the agent gains an incentive to act against the principal's interests. If a liberal lawmaker delegates to conservative civil servants, for example, then the agents have less of an incentive to pursue the lawmaker's favored policies than they would if they were also liberals. Agency loss arises when the principal lacks knowledge about an agent's activities because the agent can act against the principal's interests without the principal being aware of the indiscretion. If, for example, lawmakers asks the police to enforce a restriction on public drunkenness, but lack information about agency activities, then the police may not fear retribution if they choose not to enforce the restriction (see Gerber, 2001 for examples).

Agency loss is even more likely if neither of the two statements is true. In other words, when principals have conflicting interests with agents whose activities they cannot know, delegation is likely to be abdication. The threats are greatest in these situations because agents have both an incentive and an opportunity to act against the principal's interests without fear of retribution.

When comparing the main themes of modern and early work on delegation, we see that many early scholars reached their dour conclusions because they presumed that the two statements described above were false. More recent work disputes this presumption, uncovering the many ways in which principals can induce their agents to have common interests and learn about their agents' activities. While the new work does not totally contradict the idea that delegation can become abdication, it is more precise about when this negative outcome occurs.

A central theme in recent literature shows how principals design political institutions to affect the incentives and future actions of their agents. McCubbins et al. (1987), for example, examine how legislative decisions about the structure of political institutions affect the extent of agency loss. Drawing on a wide array of actual administrative procedures, they show that lawmakers can and do set rules for agents that reduce agency loss by ensuring that people who share their policy interests are able to influence what agents do. For example, lawmakers often not only require agents to file extensive reports on their activities, but also invite interested parties from outside the agency to do the same. These interested parties are chosen because they are known to share the lawmakers' policy preferences – including them in the process makes agents more attentive to the lawmakers' policy desires. Many studies also show how lawmakers attempt to reduce agency loss by choosing agents who share their interests (i.e., by making civil service appointments on a strictly political basis: see Epstein and O'Halloran, 1999 and Laffont and Tirole, 1993 for reviews of such findings).

Future Trends

Emerging trends in world politics make understanding delegation more important than ever. Many nations delegate increased responsibility to international organizations such as the European Union and the World Trade Organization. While such actions can produce lower trade barriers and increase social prosperity, they also require national governments to transfer power to others. Many people fear that such transfers will leave nations too weak to combat critical problems. As a result, the future value of research on delegation will be tied to how well it provides political leaders with the theory and evidence they need to make wise choices when delegating to others. Fortunately, today's scholars are responding to this challenge in creative and influential ways.

An emerging trend in delegation research clarifies which ways of delegating are most effective and efficient for political principals. Lupia and McCubbins (1998), for example, use principal – agent models and laboratory experiments to distinguish the types of institutional designs that are most effective in helping principals overcome problems associated with their lack of information about their agents' activities. Their results show when a wide range of political principals (i.e., voters, legislators, and jurors) can (and cannot) learn what they need to know about their agents. Elsewhere, Epstein and O'Halloran, (1999) use substantial theoretical and empirical

research to distinguish when legislatures can (and cannot) benefit from narrowly constraining the agencies to which they delegate (see Huber and Shipan, (2000) for a review of recent studies that adopt this perspective).

Works such as these will likely increase the extent to which real-world politicians learn the most effective and efficient ways to delegate. If they do, then delegation research will continue to give governments large and small the ability to cure broader ranges of social ills – a product of great value in an increasingly complex world.

Abstract

Deliberation is the process of gathering and assessing reasons that ground the preference for some course of action over others. In its political specification, the process is aimed at drafting and issuing collectively binding authoritative decisions. After its initial conceptualization in classical Greece, in the republican Rome, and the fixation of its canons in the Middle Ages, the role of deliberation as a politico-theoretical tool has progressively lost its centrality due to the growing interest modern scholars have developed in democratic representation within large-scale societies. It was not until the 1980s that political theorists restarted discussing the virtues of deliberation in democracy. The idea of democratic deliberation nowadays plays a crucial role in the definition of political legitimacy.

Introduction

Deliberation comes from the Latin verb *deliberare*, meaning to take something off (*de-*) a scale (*libera* or *libra*) after having carefully weighed it. The word is generally taken to refer to the process of gathering and assessing reasons that ground the preference for some course of action over others. In its political specification, the process is aimed at properly drafting and issuing collectively binding authoritative decisions. The history of deliberation in political theory is intertwined with that of democracy. Only recently, however, political theorists openly embraced the so-called deliberative turn in politics and started conceptualizing deliberation as an essential feature of democratic legitimacy in pluralistic societies.

Origins: The Workings of Athenian Democracy

The concept of political deliberation has a long-standing tradition in philosophy. Its original formulation can be dated at least as far back as Aristotle's *Nicomachean Ethics* – which was probably written around 330 BC (Aristotle, 2004a: p. vii). In book III, Aristotle defines deliberation and its scope claiming that it "is concerned with what usually happens in a certain way, where the consequences are unclear, and where things are not definite," adding that – given our somewhat epistemically deficient position – "on important issues, we do not trust our own ability to decide and call in others to help us deliberate" (Aristotle, 2004a: p. 43). The reason why we do not and ought not to deliberate about "eternal things, such as the universe, or the fact that the diagonal is incommensurable with the side" is that none of these things can be effectively brought about. Essentially, we deliberate "about what is in our power" (Aristotle, 2004a: p. 42). A more systematic treatment of the concept of deliberation, specifically in its political signification, features in Aristotle's *Politics* (1998). Chapter 14 in book IV offers an overview of the three elements that Aristotle believes make up all constitutions: these are, roughly, a part dealing with the definition of procedures by means of which a polity would choose their officials, a judiciary part adjudicating controversies among citizens and between citizens and the state, and a deliberative part. The latter "has authority in relation to war and peace, the making and breaking of alliances, and laws; and in relation to death, exile, and the confiscation of property; and in relation to the selection and inspection of officials" (Aristotle, 1998: p. 125). This deliberative function can be interpreted, according to Aristotle, as involving all citizens all the time, only some citizens all the time, or some citizens sometimes and all citizens some other times. The first interpretation, all citizens involved all the time, is the intuitive (Athenian) idea of democratic deliberation. Still, there are several ways of democratically conceiving deliberation with every citizen's participation. Aristotle lists four such ways: (1) citizens might deliberate in turn, rather than all together; (2) citizens might deliberate all together only about the choice of officials, legislation, war and peace, and inspections, leaving any other deliberation to a subset of the citizenry either elected or drawn by lot; (3) the entire citizenry could deliberate about offices and inspections, about war and alliance, leaving a restricted number of issues demanding a high degree of knowledgeability to be dealt with by officials; and (4) every citizen could participate in every decision and appointed officials would only have to prepare issues for decision.

Just like Aristotle's ethics has sometimes been said to be "mere Athenian common sense dressed in philosophical garb" (Aristotle, 2004a: p. viii), so his definition of democratic deliberation is clearly inspired by, if not openly built upon, the configuration of Athenian democratic institutions. The democratic architecture of Athens (see Hansen, 1991; Ober, 1989, 1996) was progressively brought about by a series of reforms, the first of which followed Solon's appointment as *Archon* with extraordinary powers in 594 BC. The *Archons* were rulers chosen among the *eupatridai* (the nobles), and each one was endowed with some powers for the government of the city-state. Solon triggered a series of reforms that progressively turned the Athenian *ekklesia* (the general assembly of citizens), governed by the *boulé* (a council composed of selected citizens), into a democratic institution. Once Cleisthenes, almost 90 years later, managed to assume the leadership of Athens, new reforms further democratized the life of the city-state. *Isegoria*, the right for every citizen to intervene and express his or her own position, became established as one of the most

fundamental rules governing the *ekklesia*. The deliberative practice was based on the competition among different political proposals and arguments publicly presented in their support. Athenian democratic participation could therefore be seen as an attempt (probably historically the first) at including good reasons in the process of public decision-making, where citizens (or at least a subset of them) had an active participative role. Cleisthenes also introduced a draw mechanism for the access both to the *boulé* and to other public offices. In this way, the risk of aristocratic lobby formation was almost ruled out. Moreover, the *dokimasia* was established: access to public offices, regardless of whether one was elected or drawn by lot for that office, was conditional to a thorough examination. This examination was held before the *boulé* or the court, as Aristotle recalled in *The Athenian Constitution* (Aristotle, 1984: p. XLV–XLIX). The candidate was asked whether he was an Athenian citizen, whether he was a devotee of *Apollo Patroos* (the protector of the family) and of *Zeus Herkeios* (the protector of the home), whether he owned a family grave, whether he was good to his parents, whether he was paying taxes, and whether he had previous military experience. Witnesses were asked to support the candidate's claims. Finally, everyone was asked whether they had any objection. In case there was no consensus about the acceptance, a debate would start to either accept or reject the candidate.

The apogee of Athenian democracy was, however, reached just before the death of Pericles (429 BC) when the *misthoforia* was introduced. Before the introduction of this reimbursement, given to anyone who held an institutional office, citizens of the lowest social strata could not afford to comply with their political duties: if they were elected or randomly appointed, they would have suffered too high losses in terms of time and work to sustain themselves. The formal right of access to a public office or of participating in the general assembly was not enough. The *misthoforia* turned this formal right into a substantial right to participation held by all Athenian citizens (slaves, women, children, foreigners, and metics were not considered citizens and therefore could not enjoy these rights).

Medieval Deliberation

If we could indicate the classical Athens as the place and the time where deliberative democracy had its birth, it was in the Middle Ages that the tools and procedures for a good deliberative process were fixated. They were essentially based on the Aristotelian rendering of the art of rhetoric. It is to be recalled that, attaching no negative connotation to the term 'rhetoric,' Aristotle had provided a detailed taxonomy of discourses (Aristotle, 2004b: p. I.3) according to their speaker, their content, and their audience. An audience could, in turn, be conceived either as judge of or as passive spectator to a speech, and in case it acted as a judge, it could do so with respect either to future or to past affairs. Thus, following this categorization, whenever an audience is a collective supposed to judge of future things, i.e., of what course of action we, as a polity, want to pursue, then the speaker is engaging in deliberative discourse (which is contrasted by Aristotle to forensic – the speaker engaging with some audience judging past affairs – and to epideictic – the audience being a mere spectator to the orator's abilities – discourses).

Coming back to the Middle Ages, it was in the newborn universities that the rhetorical canon of deliberation as theorized by Aristotle became crystallized and routinely taught. With the birth of the European universities, around the twelfth century, the Aristotelian rational method to tackle problems worked as a common ground for all teachings in the liberal arts, particularly in the so-called *Trivium* (where logic, the art of good reasoning; rhetoric, the art of good persuading; and grammar, the art of good writing, were taught). This method was based on three main pillars: (1) the clarity of the statement of a problem, (2) the identification of an appropriate solution, and (3) its rational justification (Boniolo, 2012: p. 89). These pillars served (and may still be used) as cornerstones for the construction of proper rhetorical tools for a particular kind of deliberation central to the didactic system of medieval universities – the *disputatio*. Disputes were typically a fundamental part of academic life for medieval scholars. They were chaired by a *magister*, who would introduce a topic asking a specific question (*quaestio*) about it. The *quaestio* would generally be introduced by the formula 'whether or not' (in Latin *utrum*). Two students would then challenge each others' arguments in favor of one answer to the question. Eventually, the *magister* would stop the dispute and propose his view, hence reaching a solution, or *determinatio* (Lawn, 1993).

Although the use of the arts of the medieval *Trivium* was restrained mostly to theoretical issues and hosted by academic institutions, the structure of *disputationes* can be seen, in light of Aristotle's taxonomy sketched above, as a blueprint for proper argumentation in a public arena and therefore deployed as a standard for public deliberation.

At the end of the 1950s, the works of Perelman and Olbrechts-Tyteca (1958) and Toulmin (1958) paved the way for the development of a series of attempts at what has been called informal logic. These authors more specifically kindled a renewed interest in the Aristotelian conception of rhetoric as the art of correct reasoning intended to persuade an audience. This resulted, years later, in the development of a proper argumentative framework for public deliberation.

Republicanism and Democracy

The idea of deliberation as constitutive to proper democratic participation has been substantially underexplored in political theory, essentially until the late twentieth century. Neither the certification or moral competence nor the construction of some institution hosting argumentatively proper debates played any central role in political theorization. Nevertheless, theories of democracy have evolved over time so as to foster the sustainability of political institutions and to better account for contestation. Republicanism is one such attempt at conceiving democracy. This theory, broadly understood, has been revived by a number of contemporary scholars (the so-called "Cambridge School" of history, e.g., Skinner, 1990; Pettit, 1997) who presented and partly reconceptualized the political theories developed by Aristotle and Cicero, in the classical Greece and the republican Rome, respectively, and,

most importantly, those proposed by Machiavelli in the early-sixteenth-century Florentine Republic. These scholars, and Philip Pettit more in particular, developed a definition of liberty that can account for two major facts of political life: on the one hand that a government creates the space for freedom and on the other that the existence of some agency authorized to make use of physical violence to enforce collectively binding rules threatens that very freedom. Accordingly, liberty is not so much conceived of as the absence of interference (as just said one of the assumptions is that the government secures freedom by constraining people's liberty, thus interfering with their lives), but rather as the absence of domination, i.e., the absence of arbitrary interference. This definition is characteristic of the rhetoric of liberty in the Roman republic, where a *liber*, a free person, was more than a mere *servus sine domino* (a slave without a master). The fate of a resourceless slave, set free by his or her master, still did not depend on him or her, but rather on the mercy of others. His or her liberty was constantly threatened by the possibility of interference by others. A *liber*, instead, was necessarily a *civis*, a citizen, whose liberty the state ought to protect against arbitrary interference (Wirszubski, 1968).

Pettit, along with other authors in the Cambridge School of historiography, understands Machiavelli – contrary to the popular reception of his works as providing a toolkit for the enablement of tyranny – as a republican scholar, whose major contribution to political theory lies in the emphasis he puts on the use of proper mechanisms for elite accountability to counteract the risks associated with the unequal distribution of wealth, which in turn could be a major cause of arbitrary interference. However, according to critiques to this account of republicanism – such as McCormick's (2011) – one of the assumptions virtually all these new republicans make is, quite counterintuitively, anti-Machiavellian, meaning that it shares more with the kind of attitude of Guicciardini and other proponents of *governo stretto* (an elitist form of government famously deployed in Venice at the time) than with Machiavelli's take on the inclinations of the *popolo* (the uneducated low social strata) and the *grandi* (the wealthy) laid out in his *Discourses on Titus Livy's First Ten Books*. These two opposing attitudes toward the people can be roughly summarized as confidence as opposed to skepticism, concerning the way in which the masses may participate in and contest public decisions. McCormick provides textual evidence supporting the claim that Machiavelli believed that the *popolo* was able (and actually more inclined to do so with respect to the *grandi*) to participate properly, without menacing the polity. The scarce emphasis put by Pettit, for instance, on the way toward the institutionalization of popular contestation in democracy, seems to imply that he takes Machiavelli to subscribe to the charge that the people have passions and inclinations that can hardly be controlled and their participation ought therefore to be constrained, in order to avoid arbitrary interference, i.e., domination, on the part of the majority on some minority. This is, McCormick argues, a standard elitist assumption instantiated, for example, by Guicciardini's words in his *Considerations*: "The people are too ignorant to discuss important matters freely and ably in assembly" (Guicciardini, 2002: p. I.2) and further developed by modern liberal theorists of representative democracy.

Regardless of the accuracy of McCormick's reconstruction, it is relevant to underscore the underlying argument that elitist theorists of politics may leverage on to make their case for less participatory institutions; participation by the uneducated masses might subject public decision-making to all sorts of irrationality, and this is undesirable because it might affect the output of policymaking. Therefore, it is better to simply restrain the number of people who actively take part in public decision-making.

Liberalism and Modern Representative Democracy

The growth in size of nation-states and the extension of political rights to new subsets of the populaces made representation increasingly the default option for institutional deliberative bodies. Modern political theorists therefore focused almost exclusively on the development of constitutions that would grant deliberative powers to people's representative rather than to people themselves.

As anticipated, the main argument supporting this solution is one fairly elitist in kind: in 1787, in *The Federalist Papers* (Hamilton et al., 1999) – a landmark in the history of representative democracy – Hamilton would alert to the risks linked to deliberation by the people, claiming that when in ancient republics the whole polity assembled to take collectively binding decisions, "a single orator, or an artful statesman, was generally seen to rule with as complete a sway as if a scepter had been placed in his single hand" (Hamilton et al., 1999: p. 328) and this was so because the sheer size of those assemblies made them liable to ignorance and sophistry. This detachment of political decision-making from what we might take as the people's will was equally well embodied in Burke's Speech to the Electors of Bristol from 1774 (Burke, 1949) in which he forcefully makes a case against the responsiveness of political delegates and representatives to the desires and preferences of their constituency. Reason and good judgment demanded that a legislator acted on "his unbiased opinion, his mature judgment, [and] his enlightened conscience" (Burke, 1949: p. 115) rather than on the irrational, uninformed, and potentially inconsistent intuitions of the people. The pursuit of the good of a nation, according to this kind of conception, is a rational endeavor and the more the people are directly involved, the less – allegedly – the outcome will be rational.

A somewhat analogous line of reasoning led to theories of democracy in which direct participation plays a very little role for the legitimacy of deliberative moments of a polity. Joseph Schumpeter famously crafted a definition of democracy that takes the deficiencies of the public (in particular the fact that people cannot possibly hold a rational opinion about every relevant issue) to affect so harshly the capability of an individual to 'directly' rule oneself that the only conceivable way out of this predicament is through open competition for political leadership. He therefore laid out the suggestion that "the democratic method is that institutional arrangement for arriving at political decisions in which individuals acquire the

power to decide by means of a competitive struggle for the people's vote" (Schumpeter, 2004: p. 269).

On the other hand, people who studied how to design institutions in the twentieth century did so from a thoroughly formal analytical angle, trying to envisage mechanisms that would allow for aggregating individual preferences so as to have a collective outcome consistent with those preferences, basically asking to what extent and whether at all some social welfare function, i.e., a function that aggregates individual preferences into societal outcomes, can meet a small set of minimal requirements of acceptability. Kenneth Arrow provided, in the form of an impossibility theorem, reasons why systems for the aggregation of ranked preferences are unable to satisfy a version of intuitive requirements of fairness (Arrow, 1950).

All of these attempts straightforwardly ignored the role that reasoning together about individual preferences might play in forming those preferences and then in making collective decisions.

Late-Twentieth-Century Rediscovery: The Deliberative Turn

For the most part of the twentieth century, political theorists have been occupied with the definition of some proper way of aggregating individual or group preferences so as to have institutions that would reflect the people's will. This favored the choice of bargaining over deliberation as a means for collective decision-making and encouraged the rather formal kind of analysis developed by rational choice theorists.

In the early 1980s, however, a number of theorists of democracy promoted a rediscovery (and a partial redefinition) of the concept of deliberation – trying to voice widespread dissatisfaction with the workings of contemporary representative democracies – contributing to what has been called the 'deliberative' turn in political philosophy. These theorists argued that democratic legitimacy demands inclusive and discursively appropriate participation. As John Dryzek put it, "[o]utcomes are legitimate to the extent they receive reflective assent through participation in authentic deliberation by all those subject to the decision in question" (Dryzek, 2001: p. 651). Even though a host of interpretations of this requirement have been articulated, most of the attempts share at least two main principles: (1) collectively binding decisions ought to be taken by all those affected by the decisions and (2) the process of collective decision-making ought to be the result of a discussion conforming to the standards of public reason among free and equal citizens (Elster, 1998: p. 8). Proper communication among equals is said to be capable of transforming one's uninformed and prejudicial preferences into well-formed preferences, i.e., preferences that fall within some logically consistent architecture of preferences and whose terms are well-defined and shared. This would in turn result in some consensus about decisions that bind the polity. Within this framework, scholars were led to hypothesize and argue what features of a speech situation would bolster the transformational potential of deliberation. German philosopher Jürgen Habermas (1990) compiled a list of rules that, when satisfied, contribute to the construction of what he named an ideal speech situation, one in which every competent speaker is allowed to present arguments and challenge others' assertions.

Principles of Deliberative Democracy

Gutmann and Thompson (1996, 2004) have provided one of the most compelling articulations of the tenets of deliberative democracy. The fact of irreducible moral disagreement, the moral disagreement residual to most collectively binding decisions, in societies truly pluralistic about values poses a tough challenge to democratic institutions. Deliberation, according to Gutmann and Thompson, helps facing at least four main issues that arise in this context. The first one is the paucity of resources that, as a society, we can allocate to specific needs. Someone will always be disappointed with a decision allocating scarce resources and somehow rightly so. He or she will have had less than others did. It becomes therefore essential that this kind of decision is extensively discussed and that everyone has their chance to challenge the arguments supporting it, thus being able to recognize its rationale. Secondly, political actors have very limited generosity. Democratic deliberation helps nourishing people's public-spiritedness, inviting everyone to put themselves in one another's shoes, hence fostering the recognition of common interests. Thirdly, public deliberation about morally sensitive issues allows a significant epistemic result: deliberation helps unveiling the real values behind one's preferences, further allowing for the recognition of possible inconsistencies in one's architecture of values. Finally, deliberating is a way to learn whether and to what extent as a polity we want to allow bargaining special and group interests and when, instead, reasons ought to prevail.

That being said, deliberative democracy, as influentially theorized by Gutmann and Thompson, is both a procedural and a substantive political theory. The values deliberation is supposed to foster do not constrain only how democratic societies should go about discussing issues (the procedural part) but also what can (and cannot) possibly be the result of a democratic deliberation (the substantive bit). There are three principles the authors outline that meant to explain, respectively, what reasons democratic deliberation requires, how these reasons ought to be presented, and who is supposed to provide those reasons.

First, deliberative democrats ought to value reciprocity: In its common understanding, reciprocity is a specific form of proportionality between some good I give away and some other good I receive in exchange for that. In the case of deliberation, one's proportionate concession is the formulation of their claims in terms that are, in principle, acceptable by others. Essentially, anyone properly motivated to find fair terms of cooperation ought to share a disposition to accept other people's arguments as long as the others are mutually bound by the same disposition.

Secondly, the principle of publicity requires that reasons for collectively binding decisions be provided publicly. Whether this entails that reasons ought to always be actually provided in public or that they must always be hypothetically or potentially made publicly available? The demands that the former

interpretation puts on political life are much more burdensome than those implied by the latter. The idea that just any decision must be taken publicly has been widely criticized, mostly with respect to the opportunity of disclosing the process that takes to controversial decisions for which accessible reasons might endanger the very good that the decision is likely to yield (e.g., strategic military decisions).

Thirdly, the principle of accountability would prescribe, ideally, that everyone presenting their claims publicly is responsible for those claims to everyone else. This is what universal accountability would demand. However, this solution looks impractical to say the least. What a realistic understanding of the value of accountability seems to require is that representatives are held accountable for at least some of their decisions (i.e., at least those decisions deemed appropriate for public scrutiny) to at least everyone who is affected by those decisions.

These principles have definitely reshaped the debate in political philosophy. It is worth noting, though, that their theoretical edifice is historically rooted, at least implicitly, in the values and principles embodied in medieval disputes.

Kinds of Deliberative Institutions

A number of institutional design proposals have been produced over the years starting from what we might call a deliberative framework informed by the principles to values just summarized. Most of these proposals have been empirically tested as a way to probe the assumptions that preferences do change thanks to the deliberative process and that the process is itself sustainable (or that it improves upon the moral sustainability of current institutions).

James Fishkin (2011) developed a method, he named 'deliberative polling,' consisting in a solution halfway between an opinion poll and an actual deliberation. Its features are very similar to those of a consensus conference, public engagement initiatives meant to include lay opinions about policy issues in actual policymaking, in which a demographically representative citizens' panel is selected randomly from a group of citizens invited to apply. Deliberative polling draws participants randomly in order to build a representative sample of the population. These people are asked a question about a policy issue. This first question is used as a baseline poll that will serve to measure the impact of the deliberation on people's preferences. Participants will then have to engage in deliberative practices about some policy issue. Briefing materials are carefully drafted and handed to the participants (these materials are also made publicly available). Parts of the events, which extend usually over a weekend, are or can be broadcasted. The deliberation happens in small groups to allow for more reflective and informed preference formation. At the end of the process, people are asked again the same question in order to gauge the impact of the process onto people's preferences. This outcome is supposed to mirror the preference people would actually entertain were they given the chance to be deliberatively informed. This approach has been criticized on the grounds that it can be characterized as a disguised form of aggregative democracy, given that preferences are simply counted at the end of the process and no genuine collectively deliberative outcome results from the polling.

Citizens' juries are minipublics that make no attempt at gathering a sample representative of the population. In fact, participants are drawn by lot in groups of 10–20 people. During meetings that develop over a couple of days, they are exposed to information presented by experts. Questioning of the experts is allowed, and participants might also call upon new witnesses to the panel. Meetings are usually open to everyone willing to attend. Deliberation within the group is directed toward the production of a recommending output, generally in the form of a report to be submitted to some relevant authority, which is typically also the sponsoring institution for these encounters and is bound to reply to the submission by either enforcing its recommendations or saying why it decided not to (Smith and Wales, 2000: p. 55).

The Account of Legitimacy and the Difficulties of Deliberating in the Real World

The account of legitimacy underlying deliberative democracy encounters a series of difficulties. Two of them, in particular, seem to pose a serious challenge to the practice of deliberation in the real world: on the one hand, in fact, deliberation requires that legitimate decisions be taken by the highest number of people that one can possibly hope for, but the more people participate in a debate, the less the likelihood that their participation will genuinely live up to deliberative standards (it will be very unlikely that people actually have time to give and heed reasons). Boniolo suggested a rough calculation concerning the hypothetical feasibility of a genuinely deliberative and democratic Athenian *ekklesia*. Approximately 6000 citizens used to participate in the assembly and assuming "each […] had spoken for, say, 10 minutes, then a full round of opinions would have taken 60 000 minutes, or 1000 hours, which are equal to about 42 consecutive days. Suppose they had slept for 12 hours during the night, then 84 days would have been necessary" (Boniolo, 2012: p. 80). Clearly then, the prospect of having a literal implementation of deliberation would be ill-suited to democratic societies.

On the other hand, even assuming that people will be able to participate properly (i.e., will have the necessary amount of time and skills), it is hard to see why they would do so in practice, meaning there are very few reasons that would succeed in motivating widespread participation. Parkinson calls these two problems the scale and the motivation problems of deliberative democracy (Parkinson, 2006).

These issues seem to affect quite radically the tenability of deliberative democracy as a practicable ideal. Some solutions have been suggested in order to redress these difficulties and ameliorate the ideal of deliberative democracy. In particular, there are competing ways of conceiving deliberation in democracy, and they all can be said to lie along a continuum that goes from micro conceptions to macro conceptions of deliberative democratic institutions. At the former end of the continuum are ways of conceiving deliberative democracy that rely upon microscale deliberations among a very limited number of participants abiding strictly by the procedures of public reasons. At the other end of the continuum, deliberation is conceived as a multithread conversation, involving different people at different times, with less formal rules for participation. With this distinction in mind, Parkinson (2006)

elaborated a new account of legitimacy for deliberative institutions that relies on the further distinction between trusteeship and delegation. Democracy, according to his (plausible) reconstruction cannot do without representation. Representation, however, can be defined either as trusteeship, i.e., the representative can make decisions on behalf of the represented as he/she sees fit, or as delegation, i.e., the representative is bound to be responsive to the instructions of his/her constituency. The preference for one solution to the principal–agent problem over the other, in Parkinsons' account, is thoroughly context-dependent. More specifically, representatives can and ought to act as trustee when they take part into microscale deliberations in which their readiness to be persuaded is essential, whereas they could and should go back to the macro-sphere and be accountable to their constituency.

Latest Developments

The Wisdom of Crowds

A series of publications contributed to a fairly novel approach to knowledge management that goes under the label of 'the wisdom of crowds' (the name comes from James Surowiecki's (2005) book). Surowiecki has tried to leverage empirical evidence to undermine the assumption that a few well-informed people, a so-called expert think tank, would always come up with a better solution than that of some uninformed small group of individuals. More specifically, he argued that disorganized crowds, when their members are allowed to freely participate in some task (given certain additional conditions), are possibly smarter than the smartest person in that very crowd at that very task. The development of infrastructures (particularly information and communication technologies) for the lean and cheap management and replication of knowledge led Weinberger, among others, to put forth a further claim, which can be summarized in his own words concerning the networking of knowledge: "As knowledge becomes networked, the smartest person in the room isn't the person standing at the front lecturing us, and isn't the collective wisdom of those in the room. The smartest person in the room is the room itself" (Weinberger, 2012: loc.132).

These developments led to the revival of some fairly anti-elitist claims against the influence experts have on policy-making, and it also propped the elaboration of some radical projects such as Robin Hanson's 'futarchy,' proposing to deploy prediction markets on policies, i.e., markets of futures in which people bet on the prospective success of policies and the ones deemed more likely to succeed are subsequently implemented (Hanson, 2013).

None of these attempts look deliberative in the sense that citizens participate in policymaking by giving and taking proper arguments, nor the legitimacy of public decisions seems to depend, within this framework, on that process of reason giving and heeding. In fact, these proposals amount to a kind of epistemic proceduralism whereby power is dispersed, or devolved, for the main reason that devolution of decision-making powers will supposedly allow for the best epistemic outcome to emerge, i.e., it would be the best procedure to know what will make a society prosper.

The Middle Ages Reconsidered

As said, the role of the *Trivium* was regarded as pivotal for any course of studies in the liberal arts during the Middle Ages. A profound understanding of rhetoric, logic, and grammar (the three disciplines *Trivium* was articulated in) was seen as a necessary requirement for any scholarly endeavor and therefore taught during the first years of every bachelor degree. The rhetorical canon described above and deployed during disputes in medieval universities demanded that deliberations be conducted following a specific procedure (in particular, the clear statement of a problem had to precede the discussion of one's proposed solution) and that arguments and objections be compliant with standards of public reason, meaning mostly that arguments had to prove logically consistent, i.e., not fallacious or invalid.

Recently, Boniolo and Di Fiore (2010) and Boniolo (2012) developed an approach to deliberation that tries to embed similar epistemic and rhetorical requirements in the decision-making process concerning controversial issues, especially dealing with ethical questions arising in biomedical research. Devising a detailed workflow to be followed for the discussion of ethical issues, these authors propose that every deliberator acquires (or shows he/she masters already) both the relevant knowledge and the appropriate rhetorical skills.

E-Democracy

E-democracy designates the set of institutional practices enabled by new information and communication technologies (ICTs). These practices have been suggested as a potential remedy to the scarce civic engagement of citizens in today's representative democracies. Being able to participate online could lower barriers to participation in a number of politically relevant activities, thus making people more likely to engage in those activities. One of the ways in which ICTs have already had an impact on the shape and modes of political activities is campaign fund-raising. After Howard Dean candidacy to the Democratic Party presidential primaries, which proved particularly successful in recruiting resources from the generally disengaged (young citizens particularly) (Hindman, 2008), political candidates have been relying regularly on online tools such as Meetups and social networks for campaigning purposes. Watchdogging practices have also been incredibly facilitated by the progressive digitalization of public documents, spurring in turn demands for more and more open data.

Attempts at democratic deliberation that rely on the Internet for their implementation, however, are still at a very early stage. Interestingly, the potential for ubiquitous availability of the Web and the increasing actual access to some decent bandwidth across different social strata accompanied by the proper skillset for the use of online tools could remedy at least part of the abovementioned scale problem, lowering costs for mass online deliberations.

Abstract

This article examines the basic features of the sociology of delinquency, including its foundation, evolution, and contemporary forms. Early perspectives are outlined and the contributions of scholars identified. A major methodological innovation, the self-report study, set the stage for scientific tests of theories, and attention shifted from the study of gangs to the study of delinquent behavior. Social control and social learning theories grew in popularity using the method. Recent research has returned to the study of gangs using the method. New sociological theories have been proposed and can be categorized in terms of their links to early perspectives. The article ends with a brief outline of recommendations for the future study of the sociology of delinquency.

Definition of the Field

The contemporary sociology of delinquency is a specialty in the field of criminology, seeking to understand the offense behavior and problems of youth through the use of methods, concepts, and theories characterizing the academic discipline of sociology. Delinquency itself is a legal concept which encompasses a variety of offenses or activities of nonadults. It has varied over time and jurisdiction, originally including a wide range of behaviors that would not be offenses for adults (i.e., status offenses) and vague designations of repeated activity (i.e., incorrigible). The category has narrowed over the years such that the contemporary application by the juvenile or family court is most often limited to offenses that would be criminal if the offender was an adult.

The Link to Criminology

The contemporary field of criminology involves the application of the 'scientific method' to the study of variation in criminal law, the causes of crime, and reactions to crime (Akers, 2000; Jensen and Rojek, 2009). This combination of method and substance evolved over time with a scientific methodology in place by the late nineteenth century, and acceptance of the broad, tripartite, substantive focus established by the middle of the twentieth century. Sociologists played a major role in defining and developing the field of criminology which emerged as an academic discipline housed in sociology programs. However, in the last half of the twentieth century, criminology emerged as a distinct professional field with a broad, interdisciplinary focus and a shared commitment to generating knowledge through systematic research.

Subject Matter

The sociology of delinquency has followed the tripartite path of criminology by seeking to understand variations in laws defining delinquency and other features of juvenile justice, searching for explanations of offense behavior among youth and designing and examining attempts to correct or prevent delinquent behavior. In their attempt to answer questions in these areas sociologists use scientific methods to identify patterns involving (1) relationships among people; (2) values, norms, and beliefs; (3) features of social institutions (family, education, government, religion); (4) features of environments that affect the opportunity to commit offenses; and (5) features of environments that affect opportunities for nondelinquent, conventional lives.

There are several reasons why sociology was the major scholarly home for criminology early in its development. First, delinquency is predominately a form of 'group' behavior. When focusing on youth, delinquent activities occur most often in groups. Some of these groups can be identified as gangs, but most are just groups of friends or acquaintances. Clifford Shaw and Henry McKay (1942) developed a theory of delinquency beginning in the 1920s which they intended to apply to delinquent activities embodied in groups and social organization. Second, the legal concept of juvenile delinquency itself was a social invention which emerged in cities and states experiencing rapid growth and diversification with Chicago leading the way. In Cook County, Illinois, a new type of organization, the juvenile court, was created to be a solution to the growing problem of wayward youth. The new juvenile justice system developed as an alternative to the adult criminal justice system and provided new ways to process and treat juveniles.

Founding Scholars

Three scholars provided much of the early foundation for the sociology of delinquency, Clifford Shaw, Henry McKay, and Earl Sutherland, all associated with the University of Chicago. The most consequential research for the development of sociological criminology and a sociology of delinquency was Clifford Shaw's study of Chicago (1929) which described and sought to explain the distribution of a variety of social problems in the city of Chicago. The observation that certain areas tended to keep high rates despite successive changes in the ethnic groups residing in them suggested that those problems were generated by the social conditions experienced by these groups rather than by any genetic or biological predispositions.

 http://dx.doi.org/10.1016/B978-0-08-097086-8.45021-X

In addition to the analysis of the distribution of problems among social areas, the scholars and researchers constituting the Chicago school systematically documented the activities, culture, and organization of distinct groups of people in the city of Chicago, including delinquent gangs (Thrasher, 1927). In his research on gangs, Frederick Thrasher identified regularities in the emergence of gangs that hold true today. In addition, Edwin Sutherland expanded and systematized a sociological explanation of delinquency in editions of his ground-breaking book, *Principles of Criminology*, first published in 1924. His book set the stage for subsequent theoretical debate and close to 100 years of theory and research on the sociology of delinquency.

Social Disorganization

Social disorganization theory was the first sociological perspective attributing variation in crime and delinquency over time and among territories to the absence or breakdown of communal institutions (e.g., family-heads, pastors, school organizations, and local officials) and communal relationships that traditionally encouraged cooperative relationships among people. The concept is defined in terms of the absence or breakdown of certain types of relationships among people, and is intimately tied to conceptions of those properties of relationships that are indicative of social or communal 'organization.' Relationships among people in a given territory are presumed to be especially 'organized' when there are high levels of involvement across age levels in activities coordinated by representatives of the communal.

In later years, numerous sociological criminologists focused on the importance of barriers to delinquent behavior with a lack of barrier comparable to social disorganization. Organized systems have strong barriers or stakes in conformity. In one of the earliest such theories, Albert J. Reiss (1951: 196) proposed that delinquency was "behavior consequent to the failure of personal and social controls." Social control was "the ability of social groups or institutions to make norms or rules effective." Walter Reckless et al. (1956) developed a 'containment' theory, focusing on a youth's self-conception as an 'insulator' against delinquency when outer constraints were weak. Jackson Toby (1957) introduced the concept of 'stakes in conformity' to explain 'candidacy' for gang involvement. F. Ivan Nye (1958) focused on the family and specified different types of control, differentiating between internal, direct, and indirect controls. Gresham Sykes and David Matza (1957) proposed that delinquent youth learned 'techniques of neutralization' that freed them to drift into delinquency. Drifters (Matza, 1964) were depicted as youth who have few stakes in conformity and are free to drift into delinquency. Scott Briar and Irving Piliavin (1965) introduced a similar concept, 'commitments to conformity.' All of these theorists drew on the social disorganization tradition by emphasizing the lack of barriers, low stakes in conformity, or weak social control.

Cultural Conflict (Cultural Deviance)

The depiction of a society as a collection of socially differentiated groups with distinct subcultural perspectives leading some of these groups into conflict with the law is a form of cultural disorganization, typically called cultural conflict or cultural deviance. There may be perfectly consistent messages conveyed within a given subculture, but they may conflict with the views of other subcultures. University of Pennsylvania sociologist, Thorsten Sellin (1938), outlined three ways in which such conflict could occur involving distinct cultural groups. Cultural conflict could occur when (1) groups with different standards overlap or interact in border regions, (2) laws of one group are extended to encompass others, and (3) distinct groups migrate into new territories. This type of theory focuses on cultural or normative conflict as the macro condition generating crime and delinquency.

Behavior acceptable or tolerated in one context may be unacceptable in another. Moreover, because laws are likely to endorse the perspectives of the more advantaged citizens and to be enforced most rigidly when dealing with the disadvantaged, lower class and other disadvantaged categories of youth will experience the greatest conflicts with official authorities. Within their own subcultural environment, they are quite normal products of successful, but subcultural, socialization. Sutherland's differential association theory was intimately linked with the concept of cultural conflict in that variation in 'definitions' among socially differentiated groups in society was the macro condition that allowed associations to be 'differential.' The most prominent cultural conflict theorist in subsequent decades was Walter Miller (1958) who argued that the focal concerns of lower class youth led them into careers of gang delinquency.

Labeling Theory

In 1938, Frank Tannenbaum, a Columbia University sociologist, proposed an age-graded version of conflict theory emphasizing 'the dramatization of evil' where the normal street activities of youth brought them into conflict with their surrounding community. The more attention paid to youthful transgressions, the more serious their involvement in delinquency. This perspective provided the foundation of a theory emphasizing labeling processes. The theory was elaborated by Edwin Lemert (1951), Howard Becker (1963), and Edwin Schur (1971).

The theory focused on the creation of and changes in the legal categories applied to people and their behavior, circumstances affecting the actual application of legal labels, and the individual and societal effects of the labeling process. The focus was not on the causes and correlates of deviant acts but on the social and political construction of the rules defining acts as deviant and the labeling process involved in applying and enforcing those rules.

Anomie, Strain, and Subcultures

Social disorganization, cultural conflict, and the beginnings of the labeling theory had developed by the end of the 1930s. A fourth theory emphasizing a specific type of disorganization as a source of crime and delinquency was elaborated by the Columbia sociologist, Robert Merton, in 1938. Merton argued

that high rates of various forms of deviance are generated in anomic social systems where there is a strong emphasis on economic success coupled with inequality in opportunity to realize success legitimately. The pursuit of success by illegal 'innovative' means is viewed as one adaptation to strain.

Other theorists have followed the same logic introducing other forms of discrepancy between goals and means as a source of frustrated ambitions. In 1955 Albert Cohen took issue with Merton's rather instrumental view of lower class crime and delinquency and introduced emotion and anger into strain theory. He sought to explain male gang delinquency and what he believed to be the hostile, negativistic content of a gang contraculture. The source of anger and hostility was status frustration.

Another elaboration of a strain theory logic was proposed by Richard Cloward and Lloyd Ohlin (1960). They proposed that the outcome of strain varied depending on the nature of illegitimate opportunities available to youth. If adult criminal enterprises were available the outcome would be a criminal subculture of delinquent youth. In settings where organized illegitimate opportunities were not available, delinquent gangs would exhibit the characteristics of a violence prone, conflict subculture. Youth who were unable to join or succeed in conflict or criminal subcultures were double failures and candidates for retreatist subcultures. Their theory was a theoretical integration of elements of Merton's strain theory and Sutherland's theory emphasizing illegal associations and opportunities.

The Self-Report Method

Between the early 1900s and 1960s the focus of the sociology of delinquency was on theoretical development with advocates of different theories criticizing each other's perspectives. Theorists debated over the best theory, but all sought to substantiate their theories by reference to the same bodies of data providing 'facts' about delinquency – police and justice system statistics. Data compiled by 'officials' could provide information on variations by territory, race, home structure, class, and gender variation. There were no direct measures of basic concepts or of delinquency offense behavior.

Sociologists had experimented with the self-report method asking people to report on their own involvement in crime and delinquency in the 1940s. The technique gained popularity in the late 1950s with the work of James F. Short, Jr. testing Sutherland's differential association theory (1957) and F. Ivan Nye's self-report study of the family and delinquency (1958). Nye specified ways to 'operationalize' (measure) control mechanisms and related them to self-reports of delinquent behavior. Not only did these scholars show the feasibility of the self-report method in the study of delinquency, but their findings challenged conventional assumptions about social class and delinquency. Some of the patterns that had dominated discourse appeared to be products of law enforcement rather than variations in offense behavior. The focus shifted from gangs and gang behavior to self-reported offense behavior. The shift to self-reported behavior was accompanied by tests of theories using the new method.

In fact, two theories facilitated by the development of survey methods dominated empirical discourse beginning in the 1960s, Travis Hirschi's social control theory (1969) and Ronald Akers' social learning theory (1964, 1973; Akers et al., 1979). In contrast to earlier theories, neither social control theory nor social learning theory focused specifically on variations among classes or demographic categories of people. Both proposed more immediate variables that affect delinquency regardless of their distribution in the social system. Moreover, the self-report method focused on the offenses reported by random samples of youth and shifted delinquency research away from gangs and gang subcultures.

Social Control Theory

Hirschi's social control theory shared many of the characteristics of earlier social disorganization theories. When applied to delinquency the theory posited that the odds of delinquent behavior were low when youth were emotionally bonded to others (attachment), committed to conventional goals (commitment), accepted laws as morally binding (belief) and were occupied in conventional activities (involvement). While most of these variables had been proposed in earlier theories, Hirschi's elaboration drew considerable attention because he identified crucial differences between this perspective and both strain and cultural deviance theory. Moreover, he presented empirical tests relevant to his view of those distinctions using self-report survey data. His book became the most cited work in criminology in the twentieth century.

Social Learning Theory

Akers' social learning theory focused on learning experiences that could be measured using survey data and most research on that perspective has used that methodology. As a theory of criminality, social learning theory emerged from a combinations of principles derived from behaviorist operant learning and other psychological theories stressing vicarious learning and imitation. Robert Burgess and Ronald Akers reformulated differential association theory in terms of operant learning theory in 1966, and Akers and colleagues elaborated a more general social learning theory in later works (1979). The social learning theory has been subjected to more empirical tests than any other theory of delinquency.

Contemporary Developments

The perspectives discussed above (social disorganization, cultural conflict, labeling and anomie) have not been stagnant and unchanging, and distinct contemporary theories reflect basic themes from the earlier perspectives. Jensen and Rojek (2009) categorize contemporary theories in terms of their answers to three simple questions. "Does the theory assume that it is the absence of constraints or limits on opportunity for crime that are key to the explanation of crime and delinquency?" "Does the theory incorporate or require some form of imbalance, strain, stress, or frustrated pursuit of conventional

or widely shared goals?" "Does the theory focus on normal learning processes, including socially structured schedules of reward and punishment, variable values, norms, and beliefs, and associations with people who both encourage and discourage crime and delinquency?"

Extensions or Reformulations in the Social Disorganization/Social Control Tradition

Six theories can be classified as variants consistent with features of a social disorganization framework: (1) routine activities theory, (2) broken windows theory, (3) self-control theory, (4) informal control/life course theory, (5) social support theory, and (6) collective efficacy theory.

Routine activities theorists (Cohen and Felson, 1979; Cohen et al., 1981; Felson, 1998) propose that variations in crime can be explained by variations in routine activities of everyday life that affect the availability and vulnerability of people and property as targets. Temporal variations in crime rates can reflect increases or decreases in the availability of unprotected targets. The theory does not introduce any form of unusual 'pressure' to explain variation in crime.

'Broken windows' theory was proposed by Wilson and Kelling in 1982 and had a major impact on the operational theories of many police departments in the United States. The theory was based on the idea that there are observable signs of 'social disorder' in an area such as broken windows, grafitti, and abandoned cars and that removing those signs can have an inhibiting affect on crime.

Advocating a 'general theory' of crime, Gottfredson and Hirschi (1990) propose that variations in crime, delinquency, and other forms of rule-breaking can be explained by variations in the sheer possibility of engaging in an activity (opportunity) together with variations in a characteristic of individuals referred to as 'self-control.' In this version of control theory, external forces work in two ways. First, there are structured variations in the opportunities to commit some forms of crime (e.g., teenagers are unlikely to be involved in corporate fraud). Second, external variations in parental supervision and socialization are viewed as the source of variations in self-control.

Another perspective falling within that tradition is Francis Cullen's 'social support' theory (1994). Cullen proposes that 'social support' should be a central 'organizing' concept for criminology and adopts a definition of social support as "the perceived or actual instrumental or expressive provisions supplied by the community, social networks, and confiding partners." Sampson and Laub (1993) propose a 'life course' theory of crime and delinquency that addresses persistence and desistence in offending based on an 'age-graded' theory of 'informal social control.' It is called a life course theory because it focuses on how people change over time. It can be classified as a version of social control because it focuses on the role of conventional institutions and investments in explaining age variation.

Sampson and various colleagues (Sampson et al., 1997; Sampson and Bartusch, 1998; Sampson and Raudenbuch, 1999; Sampson, 2002) and Ralph Taylor (2001: 128–129) introduce a new concept, 'collective efficacy,' (social efficacy for Taylor) as the key to understanding ecological variations in crime and delinquency. When residents do get along, work through local organizations to better the community and take steps to informally control trouble in their neighborhood, they are high in collective efficacy.

Extensions or Reformulations in the Anomie/Strain/Status Frustration Tradition

There are also contemporary twists on anomie/strain/status frustration theories: (1) self-derogation theory, (2) integrated strain-bond theory, (3) general strain theory, (4) institutional anomie theory, and (5) control-balance theory. Such theories are classified here as part of the strain tradition in that they all include an imbalance of some kind that provides the motivation for violating laws.

Howard Kaplan (1975, 1980) and Delbert Elliott et al. (1985) were the first theorists to propose an integrated theory in which variables from strain, social control, and differential association theory all played a role in the explanation of delinquency. However, their perspectives fall in the strain/frustration tradition because they focus on frustrations in goal attainment as the process setting youth in search of a solution. Elliott viewed his perspective as an integration of strain and social control theory while others (Akers and Sellers, 2004) view the theory as quite compatible with differential association and social learning theory.

The title of Robert Agnew's most recent work is *Pressured Into Crime* (2005). Neither social disorganization/control theory nor cultural conflict/differential association theory require a 'pressure' to explain crime. General strain theory is a motivational theory and introduces pressures as a major source of motivation for crime and delinquency. It is called a 'general strain' theory because it is not limited to the specific types of frustrated goal achievement emphasized in the original development of the theory (i.e., failure to achieve positive goals).

Charles Tittle (1995) has developed a very elaborate theory of deviance in general named 'control-balance' theory. Because it includes control in its title it may be tempting to categorize it with social control theory. However, Tittle argues that deviant behavior 'Deviant is a device' that 'helps people escape deficits and extend surpluses.' Early strain theorists emphasized failures to achieve widely shared success goals, and Tittle incorporates problems in achieving more basic human needs or goals as providing motivation or 'predispositions' for deviant action.

In *Crime and the American Dream*, Steven Messner and Richard Rosenfeld (2001) propose yet another version of a strain/frustration theory – an 'institutional anomie' theory in which economic dominance is the cause of high crime rates in the United States compared to other nation. While the theory is clearly anchored in the anomie-strain tradition, as evidenced by its focus on 'anomic cultural pressures,' the mediating mechanisms linking economic dominance to crime are quite compatible with social disorganization/social control theory. Not only do anomic 'cultural pressures' directly facilitate crime, but they also weaken (or prevent the development of) other social institutions as sources of informal social control.

Martin Sanchez Jankowsi's *Islands in the Street* (1991) and Elijah Anderson's book, *Code of the Streets* (1999), fall in the strain tradition because the 'character' traits or 'codes' they

identify as a characteristic of gang youth are not a reflection of a wider subculture passed on through normal processes of socialization from generation to generation. Rather, gang delinquency is depicted as a response to limited resources or the irrelevance of more conventional culture to life on the streets. Based primarily on observational or ethnographic evidence, Jankowski argues that the key to understanding movement into gangs is a type of 'social character' called 'defiant individualism.' When a theorist emphasizes 'defiance' it implies more of a contraculture than a subculture.

Elijah Anderson reintroduced the notion of an oppositional subculture where self-respect requires a demonstration of toughness and maintenance of honor requires physical violence. Although the code is identified as most relevant to black youth, Jankowski's version is relevant to gang members in a wide range of ethnic groups, including whites. It should be noted that codes and characters can become 'subcultural,' if they become an enduring tradition passed on through normal learning processes in an area.

Extensions or Reformulations in the Cultural Conflict/ Differential Association Tradition

The most prominent elaboration of ideas that has been linked with the cultural conflict/differential association theory is Ronald Aker's 'social learning' theory. Social learning theorists believe that although 'definitions' play a role in the learning of conventional and unconventional behavior, such definitions do not capture all ways of learning delinquency. Social learning theory does fit with the normative conflict/differential association theory in that the learning processes are normal and can involve learning of expectations that conflict with the law. Moreover, the perspective has been expanded to include both 'micro' and 'macro' issues and is now called a 'social structure-social learning theory (SSSL).' It has been extended to apply to variations among societies as well as variations among socially differentiated categories of people within societies (see Akers, 1998; Jensen and Akers, 2003; Akers and Jensen, 2003).

Two life course theories can be considered part of this tradition as well. Terence Thornberry (1987) proposed an 'interactionist' theory that he believes integrates social control and social learning theory. It is classified here as a life course theory in the social learning tradition because the factors that influence delinquency and crime are supposed to vary by age and the stage in a delinquent career from initiation to persistence to desistence. Mark Warr (1993, 2002) has elaborated a life course perspective that specifically incorporates ideas, concepts and propositions from differential association and social learning theory.

Extensions in the Labeling/Constructionist Tradition

The labeling/social constructionist perspective has been applied to a wide range of issues using the concept of 'moral panic' to argue that many features of problem behavior are exaggerated or fabricated. Stanley Cohen (1973) is best known for his development of the concept of moral panic to explain how certain groups or episodes come to be viewed as a threat to society – a threat typically amplified by the media. The argument has been extended by Erich Goode and Nacham Ben-Yehuda (2009) to encompass forms of deviance they consider 'imaginary.' Most recently, surges in gang activity have been argued to have properties of a panic in that there may be discrepancies between any real surge in gang activity and media and police responses to it. Constructionists' positions can range from interpretations where the problem is a fabrication to milder forms where variations in some 'measurable' form of 'real world' phenomena are allowed to enter into the social construction of reality.

Marxist Theory

Several theorists (Greenberg, 1979; Schwendinger and Schwendinger, 1976; Quinney, 1980; Young, 1975, among others) have proposed perspectives which draw on ideas developed by the German social philosopher, Karl Marx. A central concept in some Marxist perspectives on delinquency is marginality. Categories of people who exist on the periphery of the economic system as an unemployed or underemployed surplus population or labor force are 'marginal' categories. Marxists attribute the high crime rate of youth to their status as a marginal category, and variations within the adolescent world reflect variations in marginality as well.

There are conflicting ideas derived from Marxist theory. For example, John Hagan et al. (1985) propose a 'power-control theory' and predict that children whose parents control other workers will be raised to take risks and to believe that they are relatively free from the control of others. Hence, children from 'command classes' will engage in more delinquency than lower status youth. Those youth who are least marginal in terms of potential dominance of others and occupational power are predicted to have the highest rates, rather than those on the periphery.

Feminist Theory

Of all the background characteristics of youths studied by criminologists, the most impressive and persistent differences in delinquency across different societies, measures of crime and delinquency, and time are gender differences. Feminist criminologists have been critical of several features of theory and research that they argue reflect a male bias. For one, there has been little research on forms of delinquency where females have rates comparable to or exceeding male rates, such as running away (Chesney-Lind, 1989; Chesney-Lind and Shelden, 1992). Since the most serious female status offenders are more likely than male status offenders to come from families where they have been the victims of male sexual abuse, the role that male dominance over women (i.e., patriarchy) can play in generating female delinquency is slighted.

Recommendations for the Future

This article outlined the history and development of the sociology of delinquency and concludes with recommendations

for the future. For one, although it is well established that variation in cultural learning is an important source of variation in delinquent behavior, the structural and historical foundation as well as the specific cultural form of those influences is totally undetermined at present. Research designed to identify the social locale of any or all of these distinct cultural forms should be a goal for the sociology of delinquency. Second, other basic sociological concepts have been used in the attempt to understand delinquency – social control, socialization, and social learning. At present, there has been no clear definition of the concepts and the differences among them. Clear and precise definitions should lead to new research establishing the independent relevance and overlap of each. Finally, social constructionists and 'realists' should pursue integrated perspectives identifying the objective and subjective foundations of the gang problem. Such research will require the use of survey methods to measure gang behavior coupled with research on media coverage.

Abstract

In dementia syndromes, the information processing capacity has deteriorated with deficits predominantly in cognitive, but also in emotional and intentional domains. These deficits compromise the social and cultural activities of a person to a critical degree. Dementia is a highly prevalent disorder in old age. Dementia diseases have to be distinguished from dementia syndromes. (1) A dementia disease process destroys certain brain structures, leading to clinically observable signs and symptoms. The most important primary dementia disease is Alzheimer's dementia. However, several other diseases may lead finally to a dementia syndrome, such as the accumulation of vascular brain lesions or strokes in cerebrovascular disease. The primary dementia diseases are progressive. Thus, the clinical syndrome follows a time course of progressive deterioration in different domains. (2) A dementia syndrome is a pattern of regularly observed signs in subjects with dementia diseases. There are several types of dementia syndromes. The dementia syndrome of Alzheimer's dementia is most common. A characteristic feature of the syndrome is the deterioration of cognitive functions – it first presents with a disorder of episodic memory. Then, the language functions, motor performance, and judgment become defective. Personality changes and disorders in the domain of affective and intentional functions are often observed.

Dementia has many aspects, and neurobiological, clinical, and family-related or socioeconomic factors have been investigated. Here neuropsychiatric aspects are presented, i.e., the signs and symptoms of dementia diseases that cause the disturbance in behavior, cognitive functions, and subjective experience of the patients, which are classified as emotional problems or personality change.

Definition of Dementia

In history, the term dementia has been subject to several changes in meaning. Today, it is defined as acquired, severe loss of mental functions due to structural brain diseases.

In dementia, the information processing capacity has deteriorated to a critical degree. Deficits are found predominantly in cognitive, but also in emotional and intentional domains. By definition, these deficits severely compromise the social and cultural activities of a person. There must be a loss of mental functions that had been acquired before (i.e., the long-standing cognitive deficiencies in mental retardation are excluded). The underlying pathology is a destruction or degeneration of brain structures; therefore dementia may not be caused by functional organic disorders such as psychoses or transient brain dysfunction like in delirium. Psychiatry is concerned primarily with the detection and diagnosis of dementia syndromes, and concerned secondly with the identification and treatment of certain dementia diseases. Dementia syndromes and dementia diseases have to be differentiated (Wells and Whitehouse, 1996).

Dementia Syndromes

Characteristic clinical profiles emerge, i.e., patterns of cognitive, affective, and intentional disturbances, because in dementia diseases the destruction or degeneration takes place with a predominance of certain brain regions or brain systems; the disease does not impair all brain structures to the same extent.

Dementia Syndrome of Alzheimer's Type

What is the clinical presentation, the pattern of deficits that characterize the syndrome of a dementia patient who suffers from Alzheimer's disease? This issue has been clarified in large longitudinal studies (e.g., Berg et al., 1990). A second question addresses the reasons for failures in activities of daily living and the need for care. The syndrome can be differentiated into cognitive signs and not primarily cognitive signs.

1. Cognitive neuropsychological signs
   a. *Amnestic signs.* Early in the time course of the dementia syndrome, deficits in episodic memory are noticed (Brandt and Rich, 1995). Recall of word lists, stories, second word of paired associates, or the reconstruction of figures drawings, which were encoded several minutes earlier, becomes increasingly impaired. The immediate recall of digits (digit span), however, remains typically unimpaired. The patients can immediately repeat a list of words but forget the words within several minutes, e.g., after a disruption by intermittent attention to other topics.

Furthermore, errors of orientation for time and space are hallmarks of this dementia syndrome. Demented persons get lost easily – at first in unfamiliar, and then even in familiar surroundings. The forgetting of data of major impact or the forgetting of actions with dangerous consequences affects activities of daily living. These deficits are characteristics of anterograde amnesia and are a consequence of mediotemporal brain damage, including the hippocampus and entorhinal cortex. Degeneration within the basal forebrain, however, may also explain a large part of the symptoms. Later retrograde amnesia starts and the recollection of data that were well known in former times becomes impaired. In later stages of

the disease, demented persons cannot remember anything but episodes from the first decades of their life.

To summarize, a dementia syndrome in persons with Alzheimer's disease presents initially with amnestic signs. Episodic memory and orientation, with respect to time and place, deteriorate, and a retrograde amnesia occurs.

b. *Language disturbance, aphasic signs.* Word finding is impaired early in the time course of the dementia syndrome of Alzheimer's type, but these and other signs of language impairment usually occur later than memory impairment. Difficulties in word finding are the most important feature of this language disturbance. Word finding is clinically observed mostly in the communication situation and in fluency tests.

As demented persons become increasingly incapable of finding correct words, in later stages of the disease, not much content is communicated: a phenomenon that has been called empty speech. Phonematic paraphasias (errors in the phonematic composition of words) or disordered syntax, which characterize various forms of aphasia after cerebrovascular strokes, are, however, not considered prominent signs in this dementia syndrome.

A lowered performance in fluency tasks is often assessed in clinical diagnosis, for example, by asking the patient to name as many animals as possible. It has been argued that fluency is not only a language test, but also a test of retrieval from semantic memory, and it is known that effective retrieval depends on nonlanguage functions. Patients with frontal lobe lesions cannot retrieve words in fluency tasks, presumably because of inefficient retrieval strategies and a defective suppression of overlearned alternative word-finding routines. Furthermore, demented persons cannot retrieve semantic features of perceived objects because of a disturbance in semantic memory (Martin and Fedio, 1983).

Later in the time course, language comprehension difficulties additionally impair the communication with a demented person. In summary, there are important language problems in the dementia syndrome of Alzheimer's type, which are predominantly caused by deficits in word finding and language comprehension.

c. *Apraxia signs.* Persons with the dementia syndrome of Alzheimer's type show errors in performing purposive movements. These errors occur although there are no obvious motor problems, such as weakness of the limb or sensoric deficits in guiding movements. It is thought that the central control of movements is defective. Apraxia in the narrow sense describes errors in specific action sequences, for example, using tools. Clinically, errors in dressing properly are encountered. Tests of apraxia include the call for imitation of limb movements or gestures.

In diagnostic schedules for dementia, constructional apraxia is tested quite often. This apraxia comprises deficits not only of the execution of movement schemata but also of the integration of visuospatial information into appropriate action (Heilman and Rothi, 1997). Copying visual designs or drawings of well-known objects, such as a clock, are defective and are performed laboriously and slowly. In addition, many demented subjects show an apractic type of writing disorder, where the action sequences of writing the individual letters can no longer be carried out correctly.

To summarize, subjects with Alzheimer's dementia show errors in performing motor tasks without weakness or paresis of the limbs, resembling central motor control deficits. Later in the time course of the disease, the impairments lead to inability to perform any practical task in the household or in self-care.

d. *Disorders of judgment.* Judgment errors and inadequate evaluation are especially relevant for the everyday functioning of demented persons and with respect to legal responsibility. In the narrow definition, erroneous or inadequate judgments, with full understanding and appreciation of the problem, can be related to the decision process in itself. This specificity is difficult to ascertain in clinical neuropsychological investigation. Therefore, more generally, inadequate judgments about the own person and the disease are considered for diagnostic evaluation.

Self-related judgments: Demented persons often cannot correctly evaluate the cognitive deficits they suffer from. Some patients describe grossly inadequate future plans. At times, not only disorder of judgment but also the psychopathological phenomenon of denial has to be considered in such situations.

Formal assessment of logical decisions, as part of the capacity for adequate judgment, is done usually by intelligence tests which demand, for example, the understanding of a logical rule within the sequence of symbols, and finding incorrect items.

In summary, inadequate or wrong judgments in self-related or logical problems are found commonly in the dementia syndrome of Alzheimer's type and may lead to legal consequences or intensify the demand of care for the patient.

e. *Other cognitive neuropsychological signs.* Demented persons with Alzheimer's diseases often show deficits in executive functions. The term 'executive functions' denotes the planning and the execution of goal-directed activities, including preparations and the monitoring of already reached partial goals. Some researchers also included self-regulation and volitional processes in the domain of executive functions. Brain structures for executive functions are at least in part localized in the dorsolateral prefrontal lobe.

Mental calculations are often tested in the clinical diagnosis of a dementia syndrome. They do not, however, test calculation function only. For these tasks, the attentional demands, and additionally, in serial calculations, the demands on working memory are high. Therefore, the reason for individual test deficits is difficult to attribute precisely.

Agnosia is mentioned in some of the dementia criteria. The classical form of object agnosia, however, is very rare. In object agnosia, the patient perceives an object – and is even able to copy the form – but is not able to grasp its meaning, to name it, or describe its attributes or functions. Demented persons

often fail to identify faces of well-known friends or relatives in later stages of the disease, but memory problems contribute to this deficit. More often, however, a perceptual deficit concerning visuospatial features of figural information can be documented by neuropsychological tests. Furthermore, the appreciation of the relation of many objects within a complex pictorial scene is often disturbed in dementia.

In addition to cognitive deficits, there are other dimensions of the dementia syndrome of Alzheimer's type.

2. Noncognitive part of the dementia syndrome of Alzheimer's type

Patients with a dementia syndrome of Alzheimer's type suffer from affective symptoms or delusions. Noncognitive signs of dementia are traditionally described by psychopathology. They are not specific for dementia. Several of these signs are commonly observed in other psychiatric diseases, for example, anxiety or restlessness. Although these signs are not as relevant for diagnosis as cognitive deficits, they present major problems for the caregivers (Cummings et al., 1996) and are often the reason for institutionalization of demented patients.

a. *Signs in the affective domain*. Early in the development of the dementia syndrome, depression is observed. Later, affect control becomes impaired. Patients may cry after minor adverse events or be aggressive or inadequately cheerful. Often the emotional state lasts only for a short period of time. The perceived emotional experience may not be as dramatic as the affective expression suggests. This phenomenon has been termed affective lability.

Affective states like aggression may also be expressed as an increased intensity. Such behaviors may often present as behavior that cannot be tolerated and may lead to institutionalization.

b. *Signs in the intentional and attentional domain*. The cerebral information processing for motivation and attention is impaired in late stages of Alzheimer's dementia. A state of 'apathy' is described quite often. A person, for example, sits in a chair for most of the time and does not move, and has no intention to start any action. Many of the noncognitive signs of the dementia syndrome are traditionally described as organic personality change. A further component of this is, as a consequence of frontal lobe disturbance, a disinhibition of action tendencies, which are usually suppressed because of cultural constraints. In addition, paranoid delusional thinking and hallucinations occur quite often within the time course of a dementia syndrome of Alzheimer's type. These also may induce aggressive behavior.

In summary, signs in multiple domains of brain functions are observed. The signs that characterize the dementia syndrome of Alzheimer's type are predominantly from the cognitive domain. However, disorders in the emotional and intentional domains have some impact for the resulting individual syndrome and for caregivers and relatives. The primary sensory and motor functions, however, are relatively spared. Accordingly, the spread of Alzheimer's pathology in the brain does not include the primary sensory and motor areas.

Frontotemporal Dementia Syndrome

The dementia syndrome of frontotemporal type is less common than the dementia syndrome of Alzheimer's type and should be described here in outline only (Brun et al., 1994). The major feature of this syndrome is a change in personality. Features of the dementia syndrome of Alzheimer's type, like predominantly amnestic and apractic signs, or a decrease in intellectual functions, are not detectable during early stages of the frontotemporal dementia syndrome.

The personality change comprises changes in the way of experiencing certain situations, in the way of reacting in certain situations, or in the way a person was used to acts spontaneously.

1. *Lack of expected reactions or actions*. The patient is aspontaneous and does not react as they did before the onset of the dementia syndrome. At times, a lack of drive is noted. As there is no emotional symptom of depressed mood and despair, this has been named pseudodepression.
2. *Disinhibition*. A lack of control of intentions, especially with respect to social norms or cultural restraints, is observable.
3. *Perseveration and stereotyped behavior*. The patient reiterates actions and is inflexible in the way of reacting.
4. *Lack of insight and disorder of judgment*, as described above (see section Cognitive Neuropsychological Signs).

In addition to the psychopathological symptoms described above, formalized neuropsychological testing reveals deficits in planning, in shifting mental set, and in working memory. The frontotemporal dementia syndrome can be identified clinically only in early stages. In late stages, mostly an unspecific terminal dementia syndrome is clinically observed.

As for the dementia syndrome of Alzheimer's type, also in frontotemporal dementia there is a heterogenous etiology with mostly genetically determined underlying diseases.

Dementia Diseases

Dementia has two sides – the individual pattern of neuropsychological or psychopathological impairments on the one side, and the damage or degeneration within the brain on the other side.

A dementia disease is a class of pathophysiological processes that result in structural brain changes that are underlying the clinical signs of the dementia syndromes (Wells and Whitehouse, 1996; McHugh and Slavney, 1998). There are many diseases of the brain that lead to a dementia syndrome.

Primary Dementia Diseases

Alzheimer's dementia disease, Pick dementia disease, or Lewy body dementia are degenerative brain diseases which up to now inevitably lead to a progressive dementia syndrome. They cause no other symptoms except symptoms of the dementia syndromes.

Neurological Diseases with Associated Dementia Syndrome

1. In some diseases the dementia outcome is obligatory. In Huntington's chorea, for example, a movement disorder precedes the progressive dementia syndrome, which regularly develops later in the time course of the disease.

2. In other diseases, the dementia outcome is facultative. These diseases are not dementia diseases per se. Vascular dementia, which is the second most frequent cause of dementia cases, is in some of its variants not associated with a dementia syndrome. Prevention of subsequent strokes, furthermore, may stop the cerebrovascular disease and prevent the development of vascular dementia.

The brain behavior relationship is interindividually variable and even the distribution of pathological changes within one disease is varying. Because in many cases the dementia disease cannot be identified reliably before neuropathological postmortem examination, the clinical dementia syndrome guides the medical decisions about treatment and secondary prevention.

Dementia Disease Etiology

Alzheimer's disease is genetically heterogenous. Many different mutations on several genes are known to cause a presenile Alzheimer's dementia. The same is true for frontotemporal dementia. Additionally, multiple causal factors are identified in senile dementia of Alzheimer's type, and it is not known whether an interaction of several factors is responsible for senile dementia cases. In some dementia cases, etiologically distinct causes are known, like in dementia following traumatic brain lesion or in a dementia patient with a series of strokes within strategic regions of the brain.

Diagnosis of Alzheimer's Dementia

The diagnosis of a dementia disease will be described for the most frequent dementia, Alzheimer's.

1. The confirmation of the disease can only be given by a neuropathological investigation of the brain after death. The microscopic analysis will reveal the amount and distribution of neuropathological features like neuritic plaques and neurofibrillary tangles.
2. There is some uncertainty as to the clinical diagnosis of Alzheimer's dementia. There are several lists of criteria proposed, e.g., by diagnostic systems, such as International Classification of Diseases (ICDs), and by consensus committees (e.g., the classification of probable or possible Alzheimer's dementia according to clinical criteria). However, the criterium lists differ considerably, and the criterium variance results in major differences in the estimated prevalence rates of population-based studies (Erkinjuntti et al., 1997).

Prospective studies of dementia syndromes improved the specificity of clinical diagnostic methods. However, at present technicians cannot distinguish between dementia diseases such as Lewy body dementia and Alzheimer's dementia with sufficient reliability.

Problems of Diagnosis of Mild Dementia in Old Age

The factors mentioned add to the diagnostic uncertainty with respect to differential diagnosis. Most dementia cases are seen in old age. The differentiation from normal aging and organic psychiatric disorders, like mild cognitive impairment or amnestic syndrome, is for many cases not easy or, especially in early stages, not possible at all.

The early detection of dementia is difficult in old age, because age in itself is associated with some cognitive decline (Reischies, 1998). Furthermore, mild cognitive deficits have to be differentiated from low talent domains of a person, and personality changes have to be diagnosed considering the premorbid personality.

Dementia Case

If the severity of the cognitive impairments of the dementia syndrome of Alzheimer's type is sufficiently high, and the severity of impairment in everyday functioning is high as well, a dementia case can be diagnosed. For these decisions, cutoff values of assessment instruments have been applied (e.g., the Mini Mental State Examination and the Global Assessment of Functioning scale).

The diagnosis of a dementia case without specification of the kind of probable dementia disease is often a clinical reality. With the advent of better diagnostic methods, however, the diagnosis of the dementia disease may be made before a clinical dementia syndrome has developed.

Time Course of Alzheimer's Dementia

There is a characteristic time course of Alzheimer's dementia over about 10 years. Interindividual variation of the time course with plateaus and progression phases is common.

Within a preclinical stage of Alzheimer's disease, cognitive decline takes place, which can be assessed by serial neuropsychological testing. Especially memory decline can be found. With memory deficits as the only clinical sign, no formal diagnosis of dementia can be made. The early phase of Alzheimer dementia thus represents an amnestic stage.

In the second stage, a clinical dementia syndrome of Alzheimer's type is detectable, which exhibits more or less the complete features of the dementia syndrome, as described above. In this stage, there are disturbances in activities of daily living, but they may still be minor.

In the stage of a severe dementia syndrome, memory loss, aphasia, apraxia, and the noncognitive symptoms have increased, and global functioning is deteriorated such that normal activities of daily living are critically compromised or no longer possible. Additionally, the noncognitive disorder disturbs the relation between the patient and the environment. Institutionalization is common.

The last stage is a terminal or vegetative stage, where no communication is possible, the patient is mostly bedridden, and has to be cared for completely.

Treatment, Professional Care, and Preventions

An increasing number of new drug treatments for Alzheimer's dementia are being investigated. However, at present only limited relief can be provided. At best, the time course can be stopped or retarded for a short time only. Training of activities

of daily living, with the goal of adaption to the specific environment, can be quite successful in order to aid care of subjects with an advanced dementia syndrome.

Major efforts must be directed to prevention, detection of risk factors, and early detection of dementia syndromes. A certain success of prophylaxis by controlling risk factors for atherosclerosis has been documented in the field of vascular dementia.

Editor's Note

Recent advances in biomedical research on the various dementia disorders are well summarized in David Kennedy (2013). Other useful updates include those by William A. Banks and John E. Morley (2003) and Samantha Loi and Edmond Chiu (2011).

Abstract

Political authority in a democracy is based on the will of the people. From its origins in ancient Greece, the advocates and opponents of democracy have argued about what this means. Who are the 'people'? How is their will to be expressed? What is the relationship between democratic politics and society? How are the rights and opinions of the minority to be protected? What are the primary threats to effective democracy and how can they be avoided? What are the dangers of democracy? In the modern era, democratic practice began with the great revolutions at the end of the eighteenth century. Throughout the nineteenth century democratic institutions developed everywhere in Europe; at the same time, the principle of popular sovereignty was applied to a range of social, economic, and national issues. Between 1914 and 1945, democracy seemed in danger, threatened on left and right by movements that used democratic methods to establish new sorts of tyrannies. In the second half of the twentieth century, however, democracy seemed to triumph over its opponents until it became, in theory if not in practice, the sole source of political legitimacy in the modern world. This has only been reinforced in the twenty-first century.
